Model-Driven Engineering

- Goals of MDE
  - developing high-quality software faster
  - avoid coding the same solutions again and again
- Principles
  - **abstraction**: build model of the target application
  - **(domain-specific) modelling languages** to define the model: less accidental details, notation close to the application domain
  - **automation**: code generation/analysis/simulation from models
- How are modelling languages defined?
  - **abstract syntax** 
  - concrete syntax
  - semantics

Index

- Bibliography

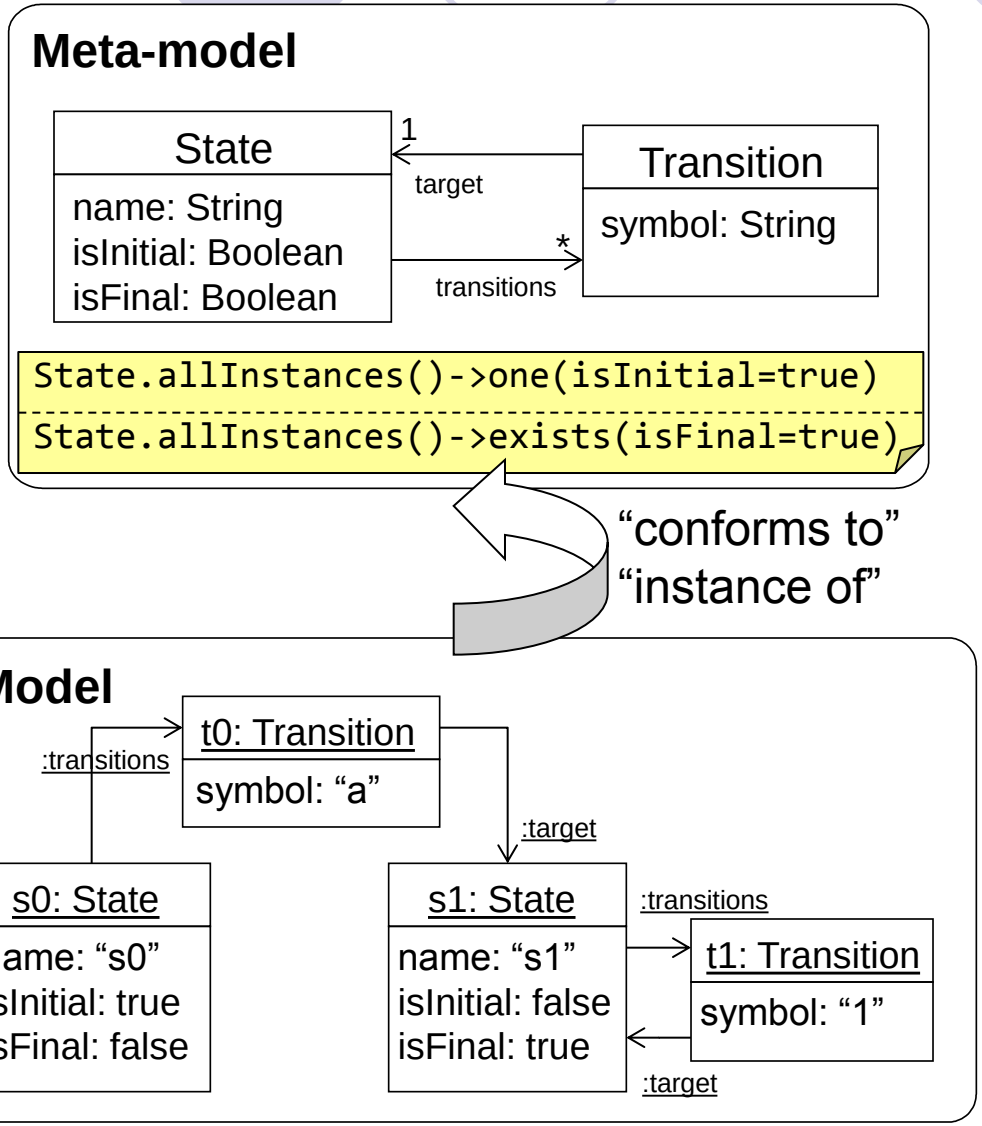
Meta-modelling

- A model is a description of the system under study, using a (modelling) language.
- A meta-model is a model that describes a language, i.e., it describes all syntactically valid models.
- A meta-model describes the abstract syntax of a language.

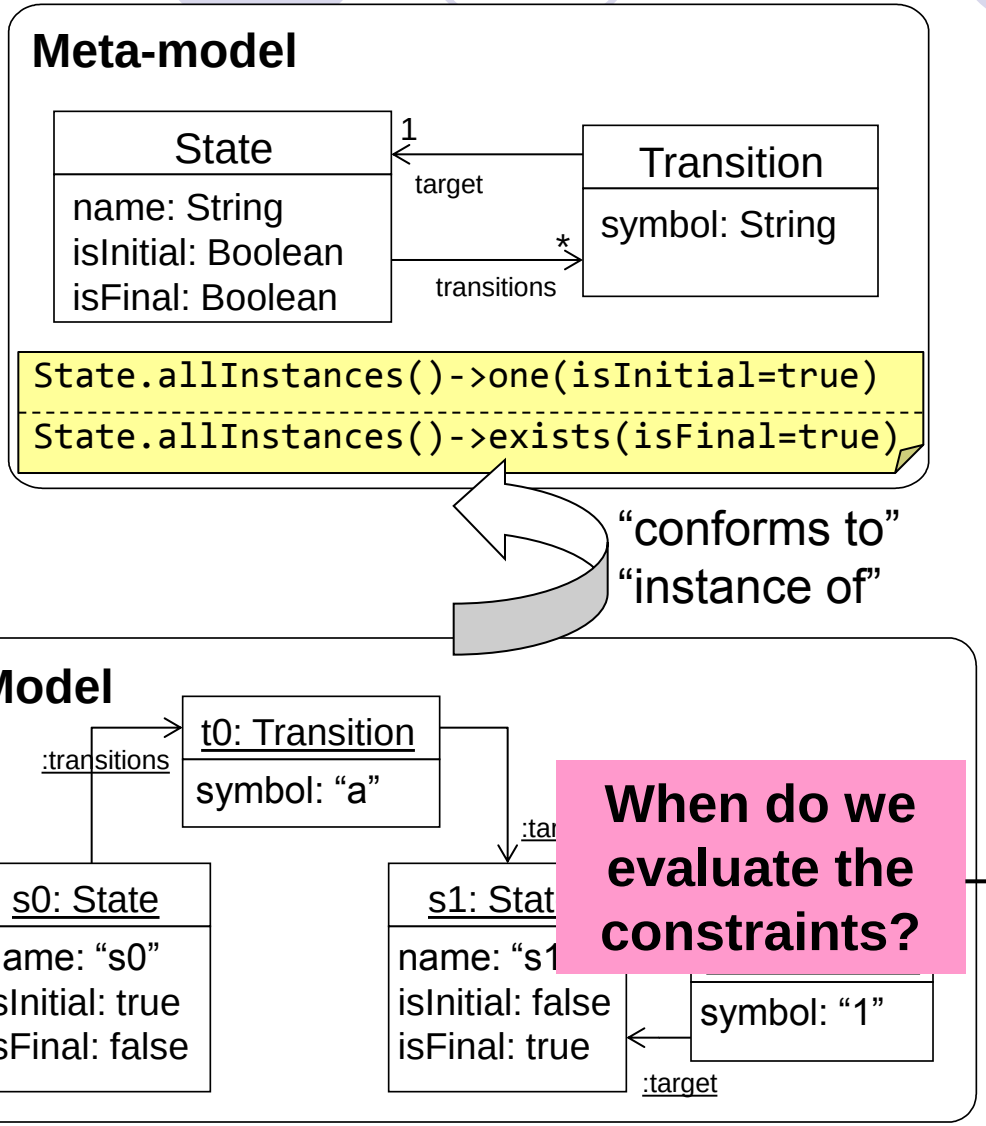
Meta-modelling

- Meta-models are usually defined using class diagrams or entity-relationship diagrams.
- Additional OCL constraints.
- Same “quality criteria” as for class diagrams:
  - class names start with uppercase letter
  - attribute and reference names start with lowercase letter
  - classes with no objects must be abstract
  - do not duplicate attributes, associations or OCL constraints (instead, create superclass with common features and constraints)
  - represent class relations by means of references
  - …

Meta-modelling



Meta-modelling



Strict meta-modelling: "*one element in meta-level n is instance of exactly an element in meta-level n-1*".

A model is a valid instance of a meta-model if the model:

- the model is structurally valid:
  - its objects are instances of classes in the meta-model.
  - its links are instances of associations in the meta-model.
- the model satisfies the following constraints:
  - cardinality in associations.
  - unique keys.
  - additional OCL constraints.

(similar to relation between class diagrams and object diagrams)

Meta-modelling

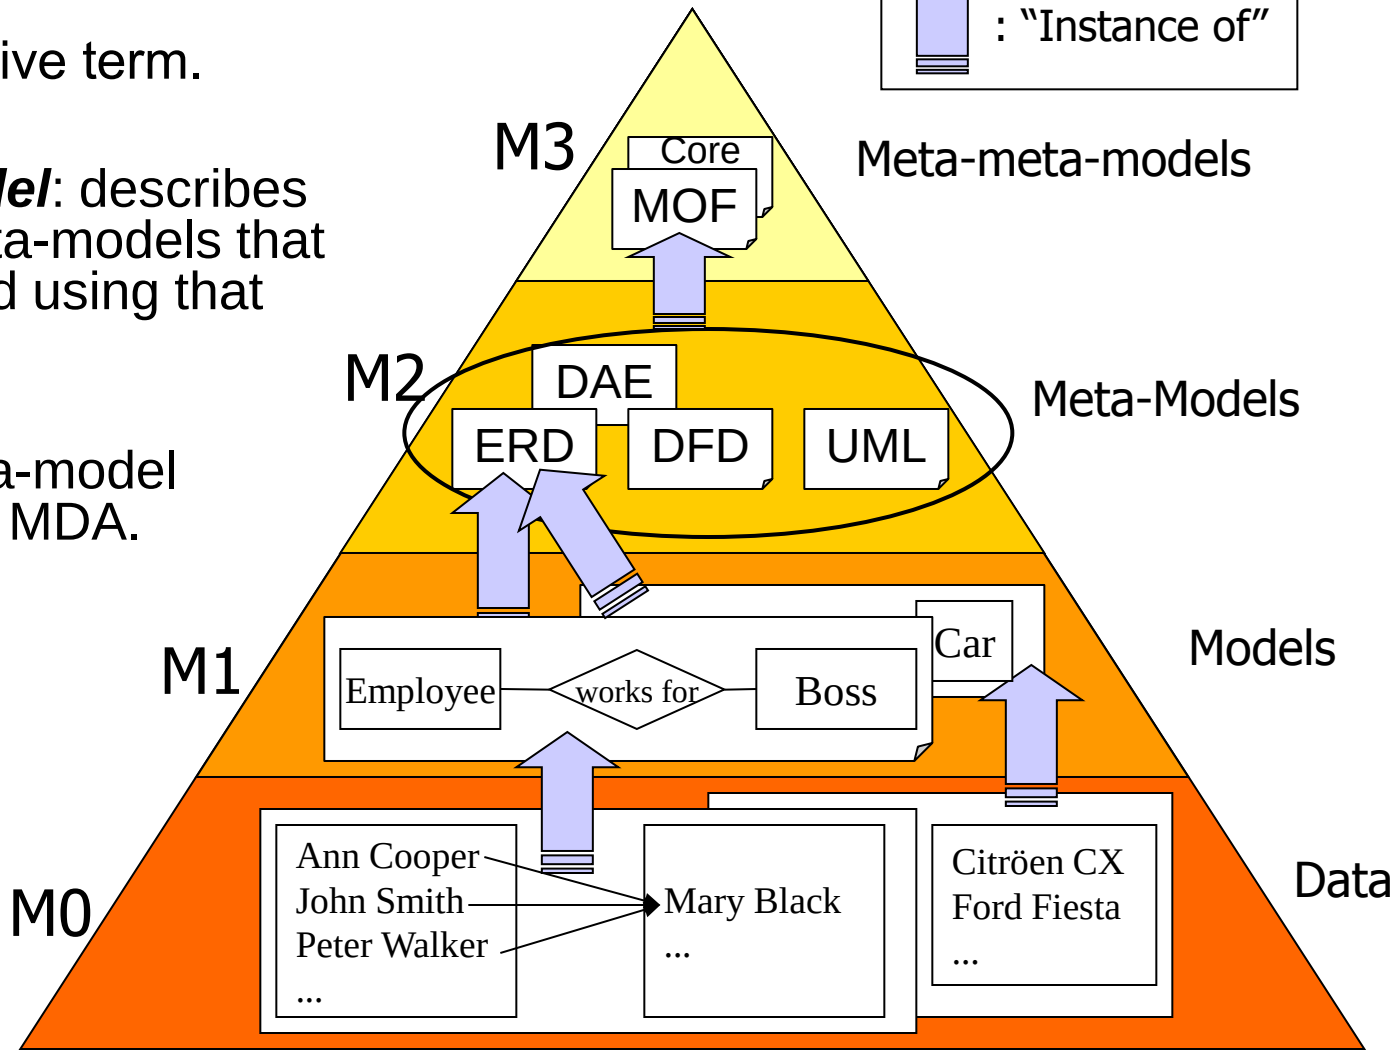
Evaluation of constraints

- When are constraints evaluated?
- Cardinality in associations:
  - If we have the cardinality interval [i..j]
    - lower bound: wait until the user wants to validate the model.
    - upper bound: report the error as soon as more than j links are created.
- Additional OCL constraints:
  - wait until the user wants to validate the model, or
  - associate constraints to editing events, as pre- or post-conditions.

Meta-modelling

Levels

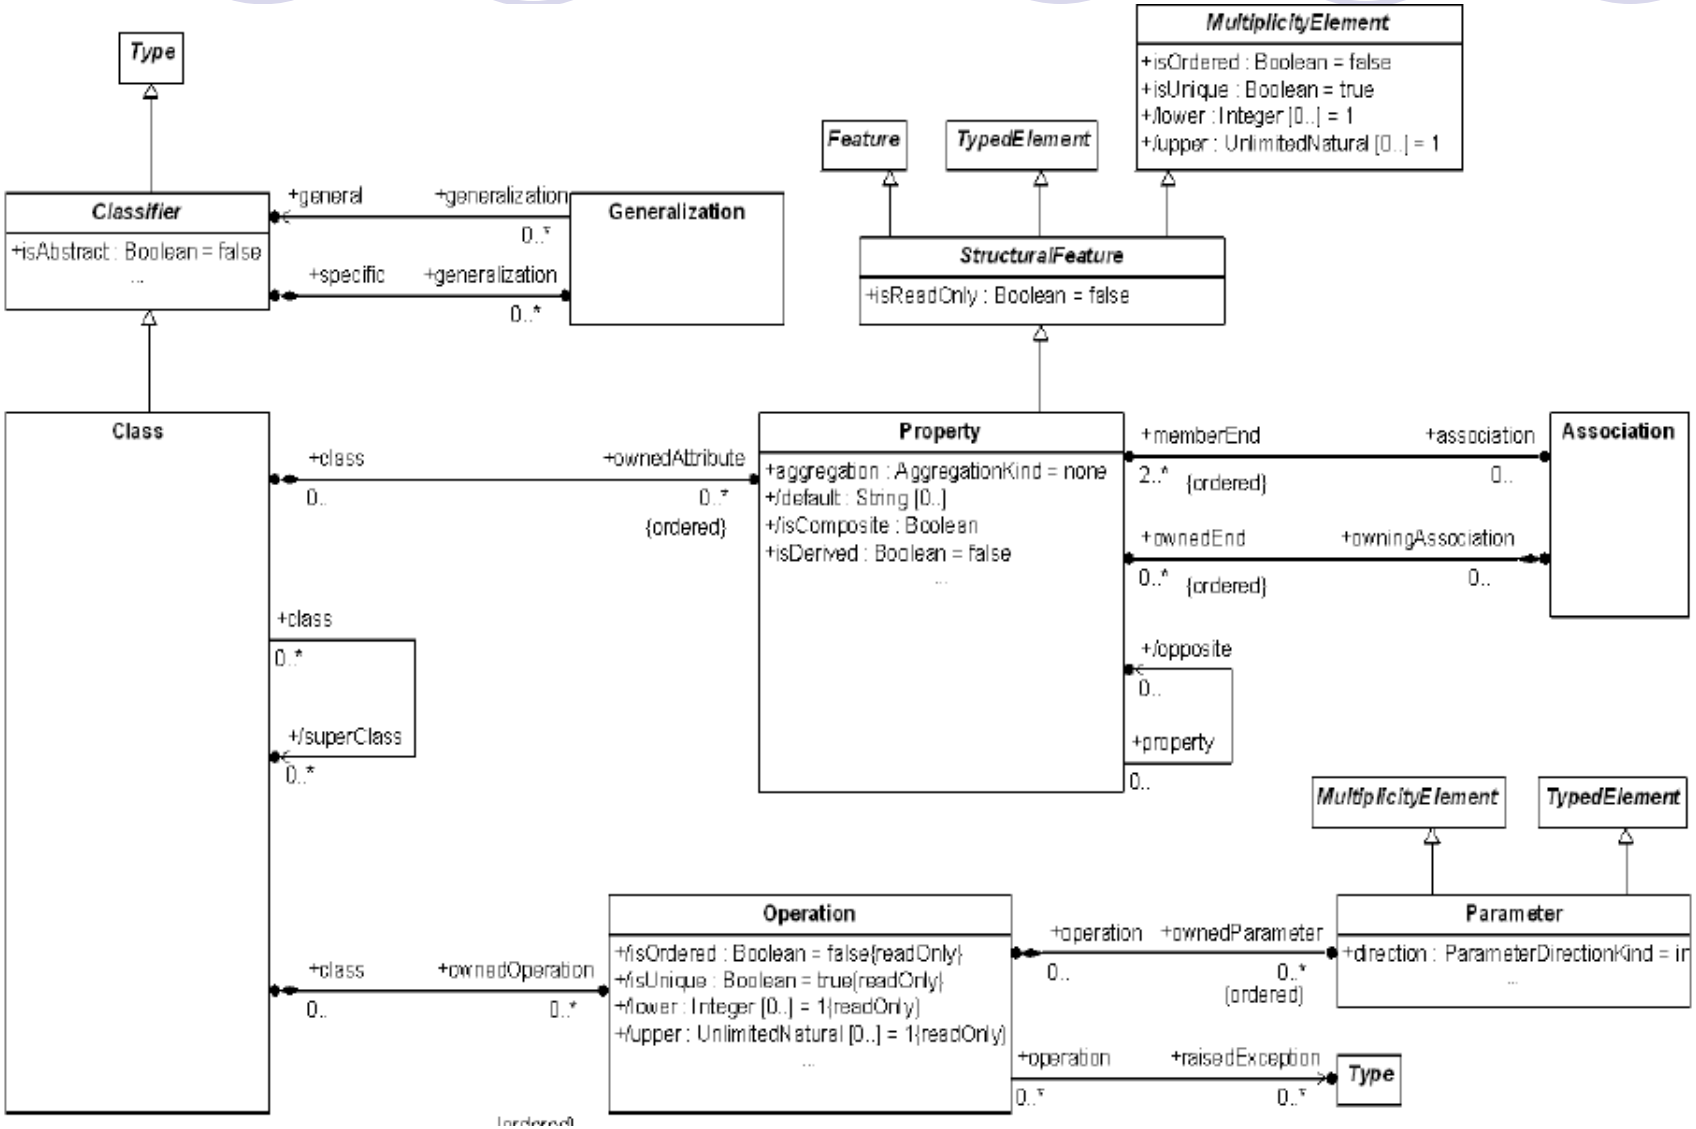
- "meta-" is a relative term.
- ***Meta-meta-model***: describes the set of all meta-models that can be described using that language.
- **MOF**: meta-meta-model proposed by the MDA.



MOF

- Meta-Object Facility (MOF) is the OMG standard for meta-modelling
  - closed architecture (4 levels)
  - strict architecture (each element is an instance of one element in the meta-level above)
- Meta-meta-model that describes a meta-modelling language, similar to class diagrams
- Two levels:
  - Essential MOF (EMOF)
  - Complete MOF (CMOF)

MOF meta-meta-model



Eclipse Modeling Framework (EMF)

- Modelling framework for Eclipse, based on EMOF

- From a data model specification described in XMI, it produces Java implementation classes for this model, and a basic tree-like editor.

- Web page: http://www.eclipse.org/modeling/emf
- Tutorials: http://www.eclipse.org/modeling/emf/docs/
- Tutorial: http://www.vogella.com/tutorials/EclipseEMF/article.html
- How to install EMF in Eclipse:
  - *Help / Install New Software*
  - *Work with*: 2021-09 – http://download.eclipse.org/releases/2021-09
  - In *Modeling*, select:
    Ecore Diagram Editor (SDK)
    EMF – Eclipse Modeling Framework (SDK)
    OCL Examples and Editors SDK
  - In *General Purpose Tools*, select:
    Eclipse Plug-in Development Environment

EMF meta-meta-model (Ecore)

Meta-model definition

- **ecore**: file with the definition of a meta-model (also called *domain model*). It contains a root object representing the meta-model, with packages containing the definition of the following elements:
  - EClass: class, it can have 0 or more attributes and references
    - EAttribute: attribute, it has a name and a primitive type
    - EReference: end of an association between two classes
      - containment
      - opposite reference
  - EDataType: user-defined attribute types
  - EEnum: enumerate type

- **genmodel**: file with information for the code generation, like path and file information.

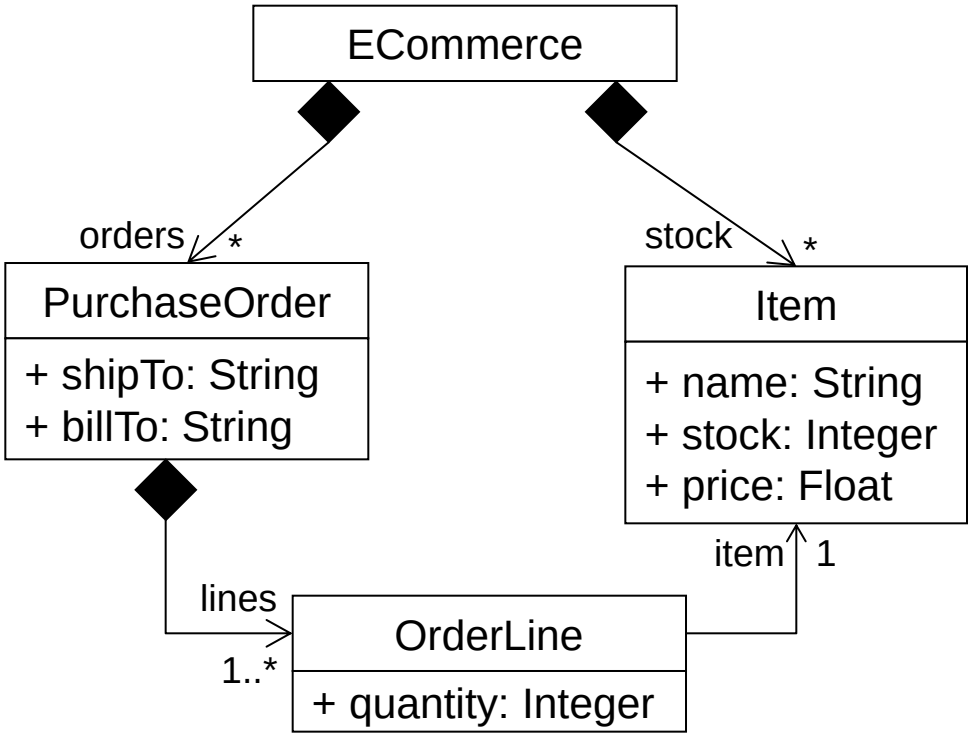
Generation of Java code

- Code generation from ecore and genmodel files:
  - model: interfaces and factories for object creation
  - model.impl: implementation of the interfaces
  - model.util: adapter factory
- Each generated interface has getters/setters methods. Each setter notifies to observers of the model.
- Each generated method is annotated with @generated. Regeneration is possible, but methods annotated with @generated get overwritten. To avoid overwriting manual changes, delete annotation or substitute by @not generated.

Generation of model editor

- Automated generation of an editor to create instances of the meta-model (tree-like editor).
- The editor is an Eclipse plugin.

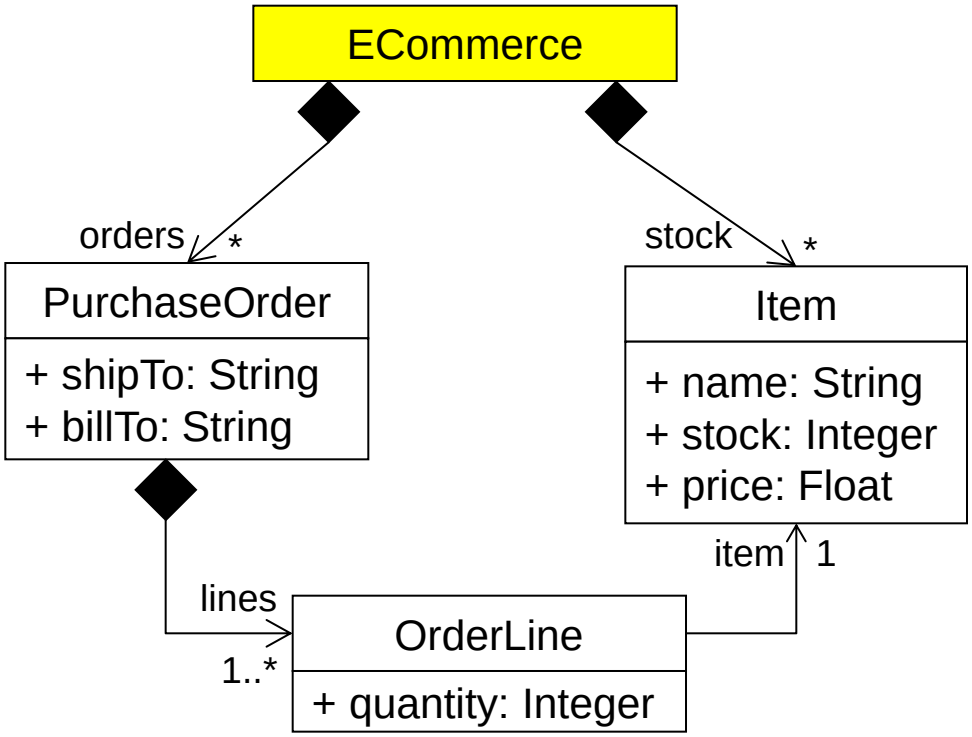
Meta-model example



Language to model the stock of products of a company, and the orders made by its clients.

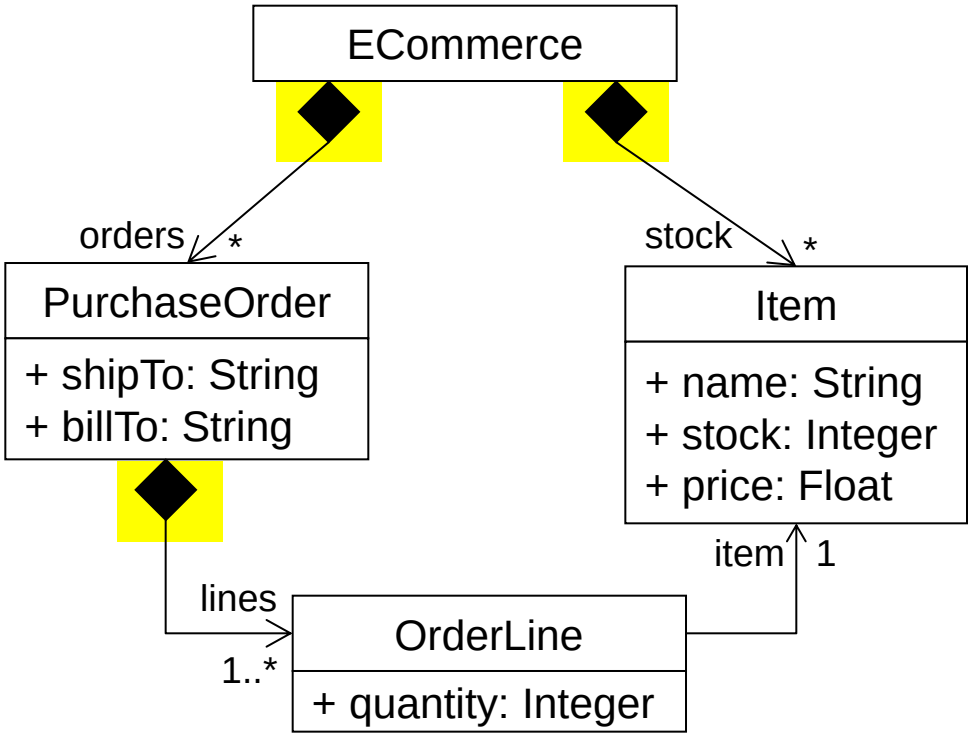
The EMF project for this meta-model is available in moodle.
Download, unzip and import the project into Eclipse.
To import a project into Eclipse: *File / Import / General / Existing projects into workspace*, and then select the project folder.

Meta-model example



An EMF meta-model must have a root class, i.e., a class that contains all the other classes directly or indirectly via containment relations.

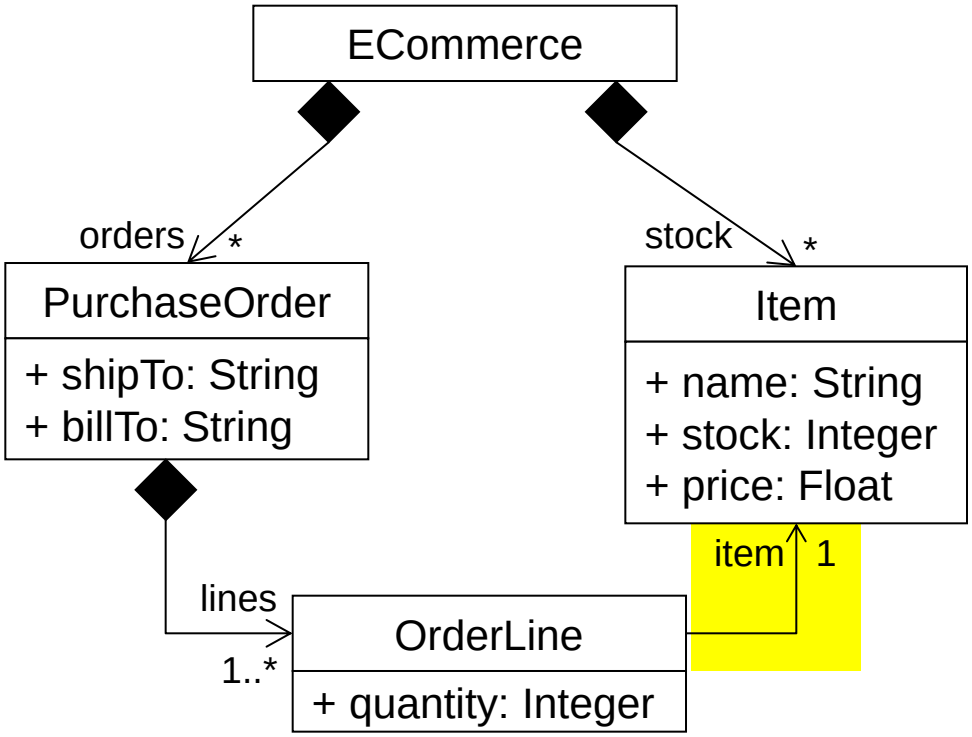
Meta-model example



Containment: each object (but the root) can be contained in another object at most. This is a limitation for models, not for meta-models.

E.g., an item can be contained in at most one commerce.

Meta-model example



Non-containment: each object can be referenced from many others (according to the defined cardinality).

E.g., an item can be part of many order lines.

Eclipse Modeling Framework

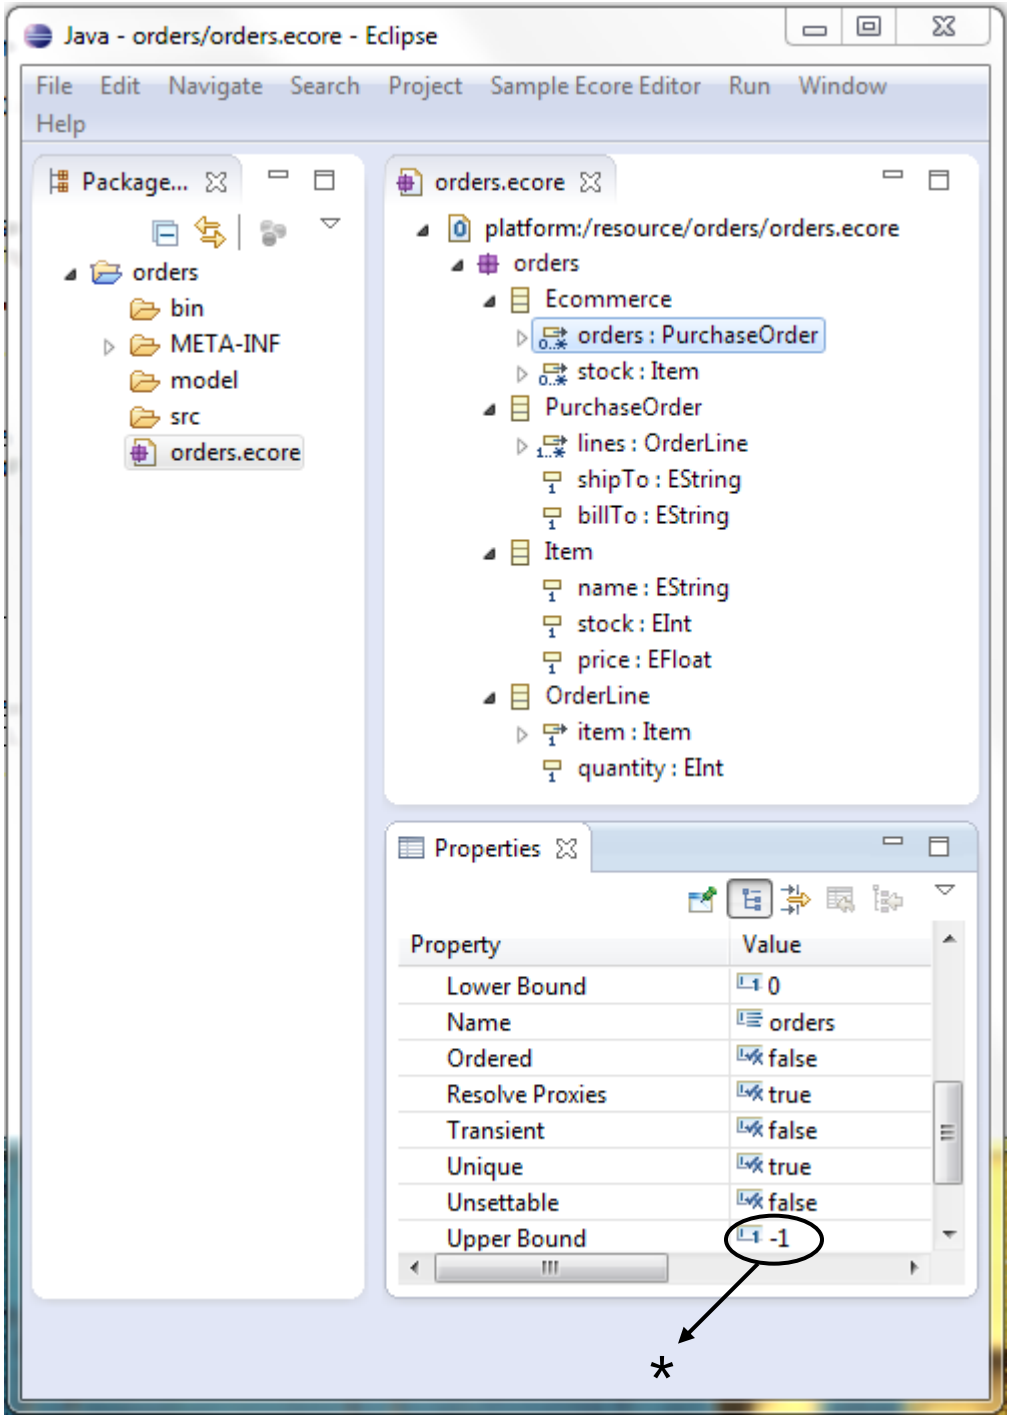
How to define a DSL and generate code

1. **Create Ecore file (meta-model)**
   - Create a new empty EMF project
     File / New / Other / Eclipse Modeling Framework / Empty EMF Project
   - Create Ecore model
     File / New / Other / Eclipse Modeling Framework / Ecore model
   - Add classes, attributes and references to diagram
2. Create EMF generator model (generator)
3. Generate Java code
4. Generate tree-like model editor

Ecore

Ecore elements

- **EPackage:** one by default
  - *Name: must start with lowercase*
  - *Ns Prefix*
  - *Ns URI*
- **EClass**: classes
  - It defines attributes and references.
  - *ESuperTypes*: parent classes
  - *Abstract*: abstract class
- **EAttribute**: attributes
  - *EType*: type (int, float, ...)
  - *Lower Bound:* minimum cardinality
  - *Upper Bound*: maximum cardinality
- **EReference**: association end
  - *EType*: referenced class
  - *Containment*: containment relation
  - *Lower Bound:* minimum cardinality
  - *Upper Bound*: maximum cardinality
  - *EOpposite*: opposite association end (for bidirectional associations)



Ecore

Textual editor of ecore files: OCLinEcore

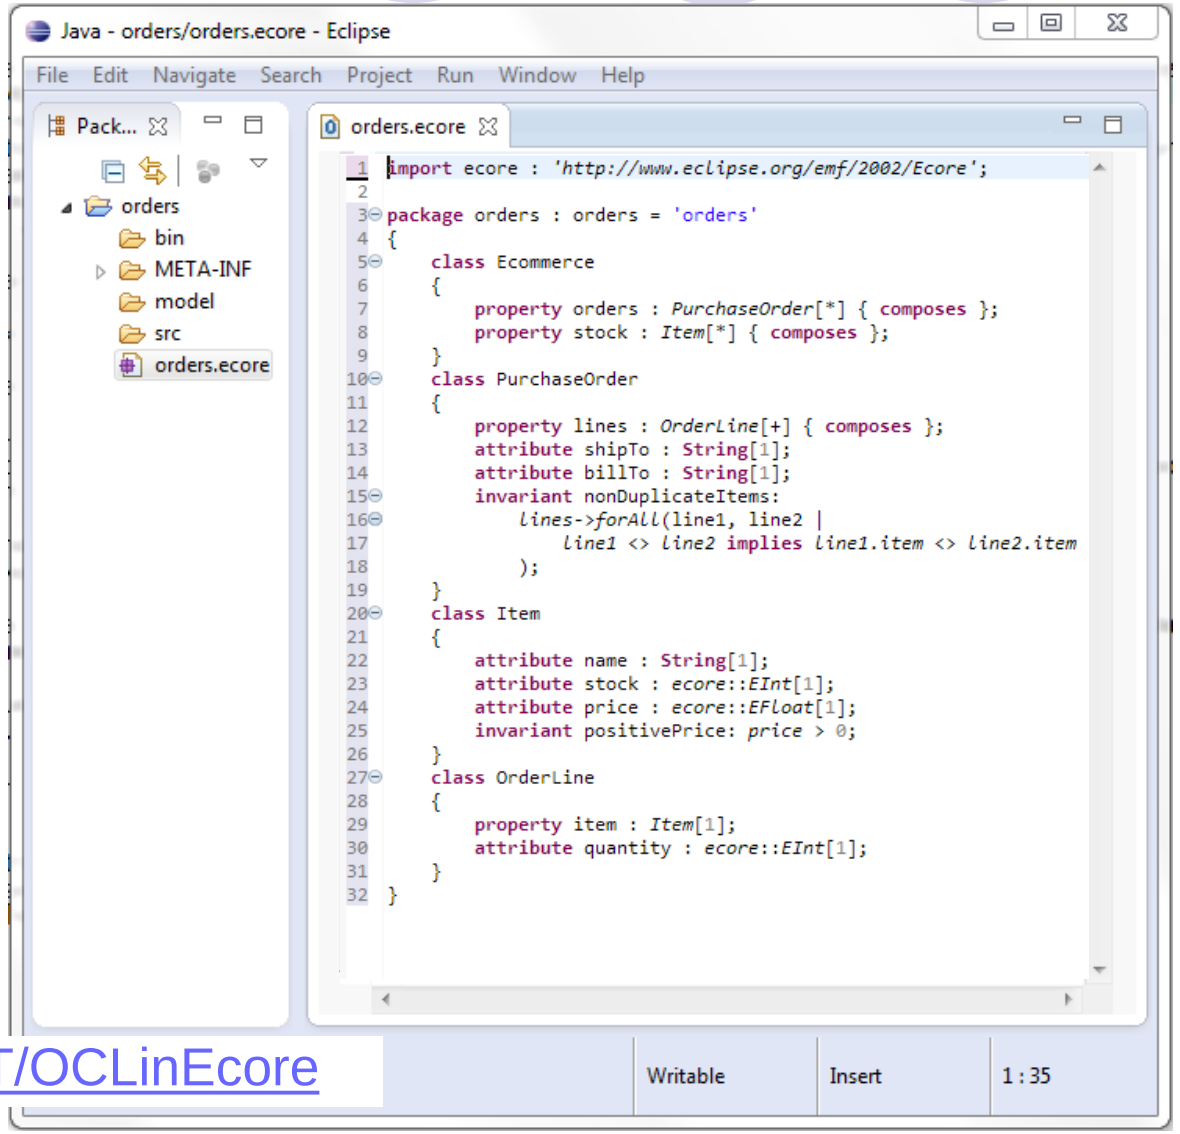
Textual editor:

Open with…
OclInEcore Editor

Tree-like editor

Open with…
Sample Ecore Model Editor

Do not edit the same model with both editors at the same time!



http://wiki.eclipse.org/MDT/OCLinEcore

Eclipse Modeling Framework

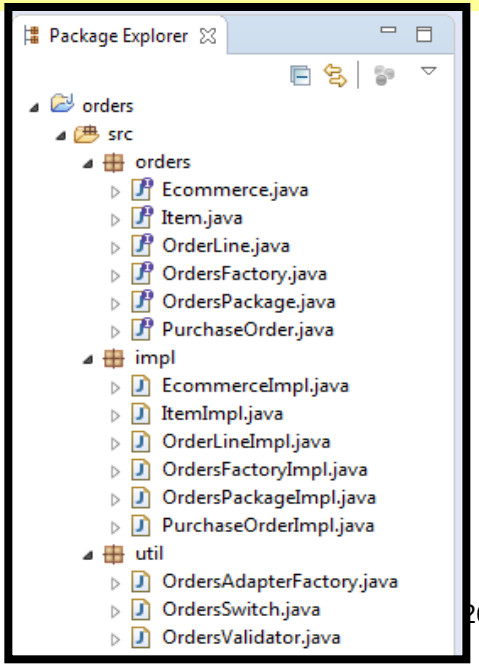
How to define a DSL and generate code

1. Create Ecore diagram (meta-model)
2. **Create EMF generator model (generator)**
   - Select ecore file, right mouse-button
     New / Other / Eclipse Modeling Framework / EMF Generator Model
   - If the .ecore file changes, reload generator model
3. Generate Java code
4. Generate tree-like model editor

Eclipse Modeling Framework

How to define a DSL and generate code

1. Create Ecore diagram (meta-model)
2. Create EMF generator model (generator)
3. **Generate Java code**
   - Open generator model, right mouse-button in root
     Generate Model Code
4. Generate tree-like model editor



Generated Java code
Factory and interfaces

A factory class is generated:

```
public interface OrdersFactory extends EFactory {
  OrdersFactory eINSTANCE = Orders.impl.OrdersFactoryImpl.init();

  Ecommerce     createEcommerce();
  PurchaseOrder createPurchaseOrder();
  Item          createItem();
  OrderLine     createOrderLine();
  OrdersPackage getOrdersPackage();
}
```

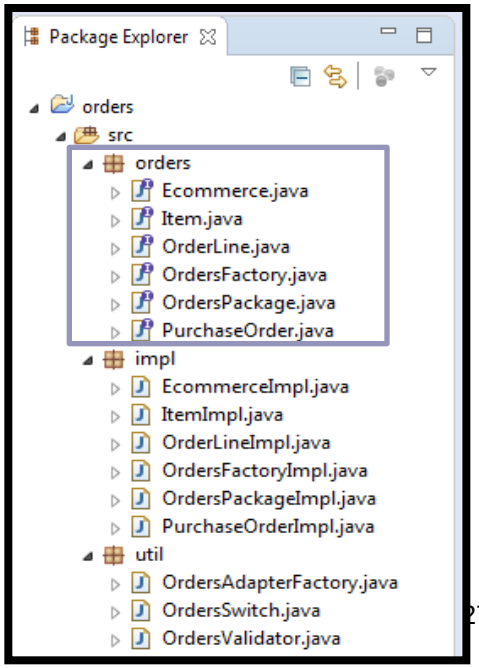
Reflective capabilities (e.g., `eClass()` returns the meta-model class, `eGet()`, `eSet()`, etc.)

For each class in the .ecore file, an interface and an implementation class are generated:

```
public interface Item extends EObject {
  String getName();
  void   setName(String value);

  int    getStock();
  void   setStock(int value);

  float  getPrice();
  void   setPrice(float value);
}
```



Generated Java code
Implementation classes

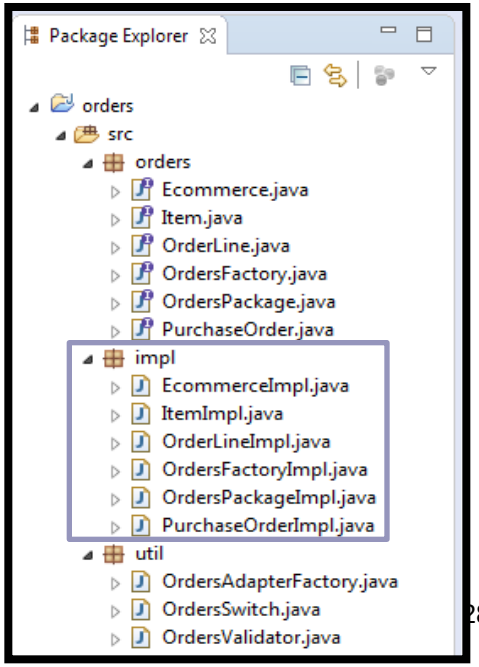
How to use the generated Java classes:

```
Ecommerce mediamarkt = OrdersFactory.eINSTANCE.createEcommerce();

Item cable = OrdersFactory.eINSTANCE.createItem();
cable.setName ("Cable VGA");
cable.setPrice(15);
cable.setStock(250);

mediamarkt.getStock().add(cable);
```

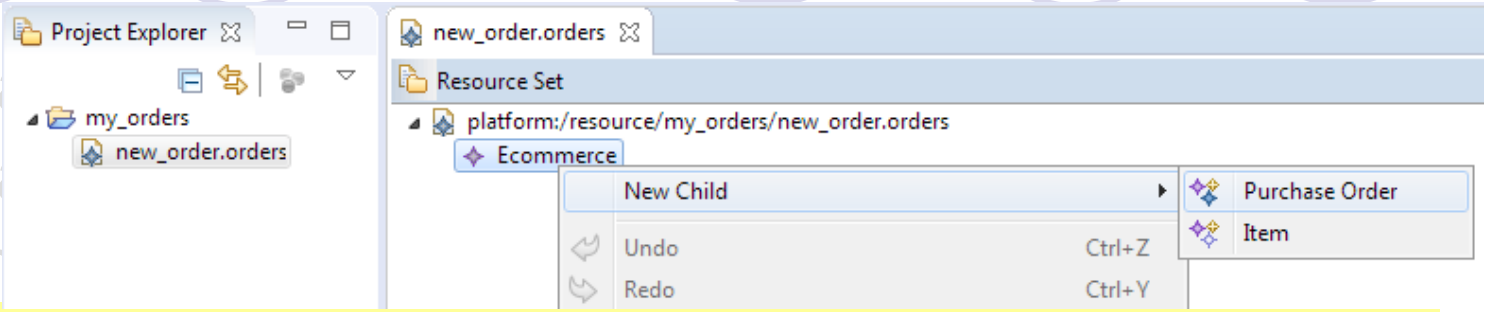
The generated methods have the `@generated` annotation. If they are manually modified, then deleting the annotation avoids the modifications are overriden when the code is regenerated.



Eclipse Modeling Framework

How to define a DSL and generate code

1. Cre
2. Cre
3. Ger



4. **Generate tree-like model editor**
   - Open generator model, right mouse-button in root
     Generate Edit Code, and then *Generate Editor Code*
   - Execute editor
     Run / Run As / Eclipse Application
     *(*it deploys the generated plug-in in the new instance of Eclipse)
   - Create empty project in new instance of Eclipse
   - Create model
     File / New / Other / Example EMF Model Creation Wizards / <new language>
     (select root class for the model, `Ecommerce` in this example)

Eclipse Modeling Framework

What to do when the meta-model changes

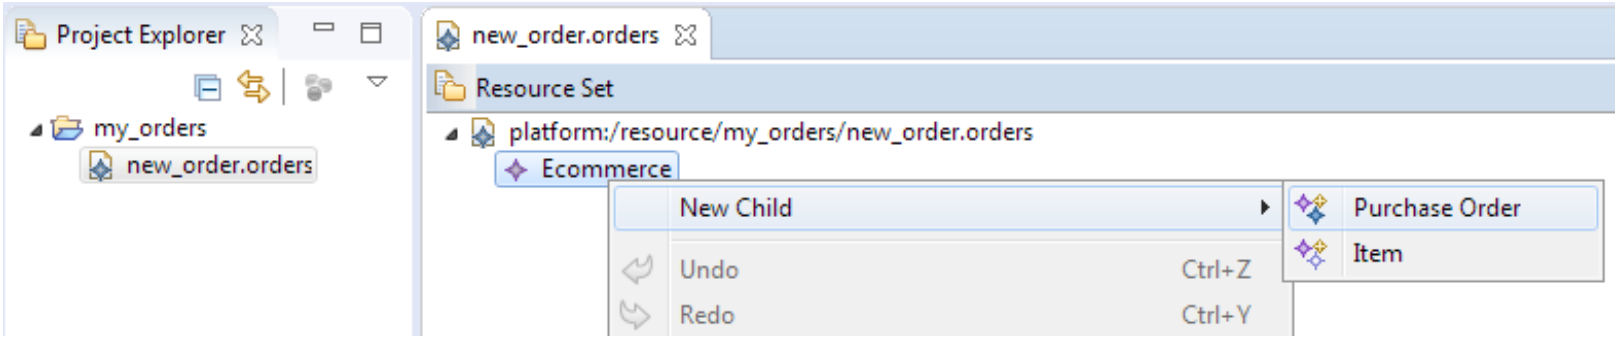
1. Create Ecore diagram (meta-model)
2. Create EMF generator model (generator)
3. Generar Java code
4. Generate tree-like model editor

If the .ecore file changes:

- reload generator model
- execute steps 3 and 4

Tree-like model editor

- Object creation using pop-up menus (for containment)

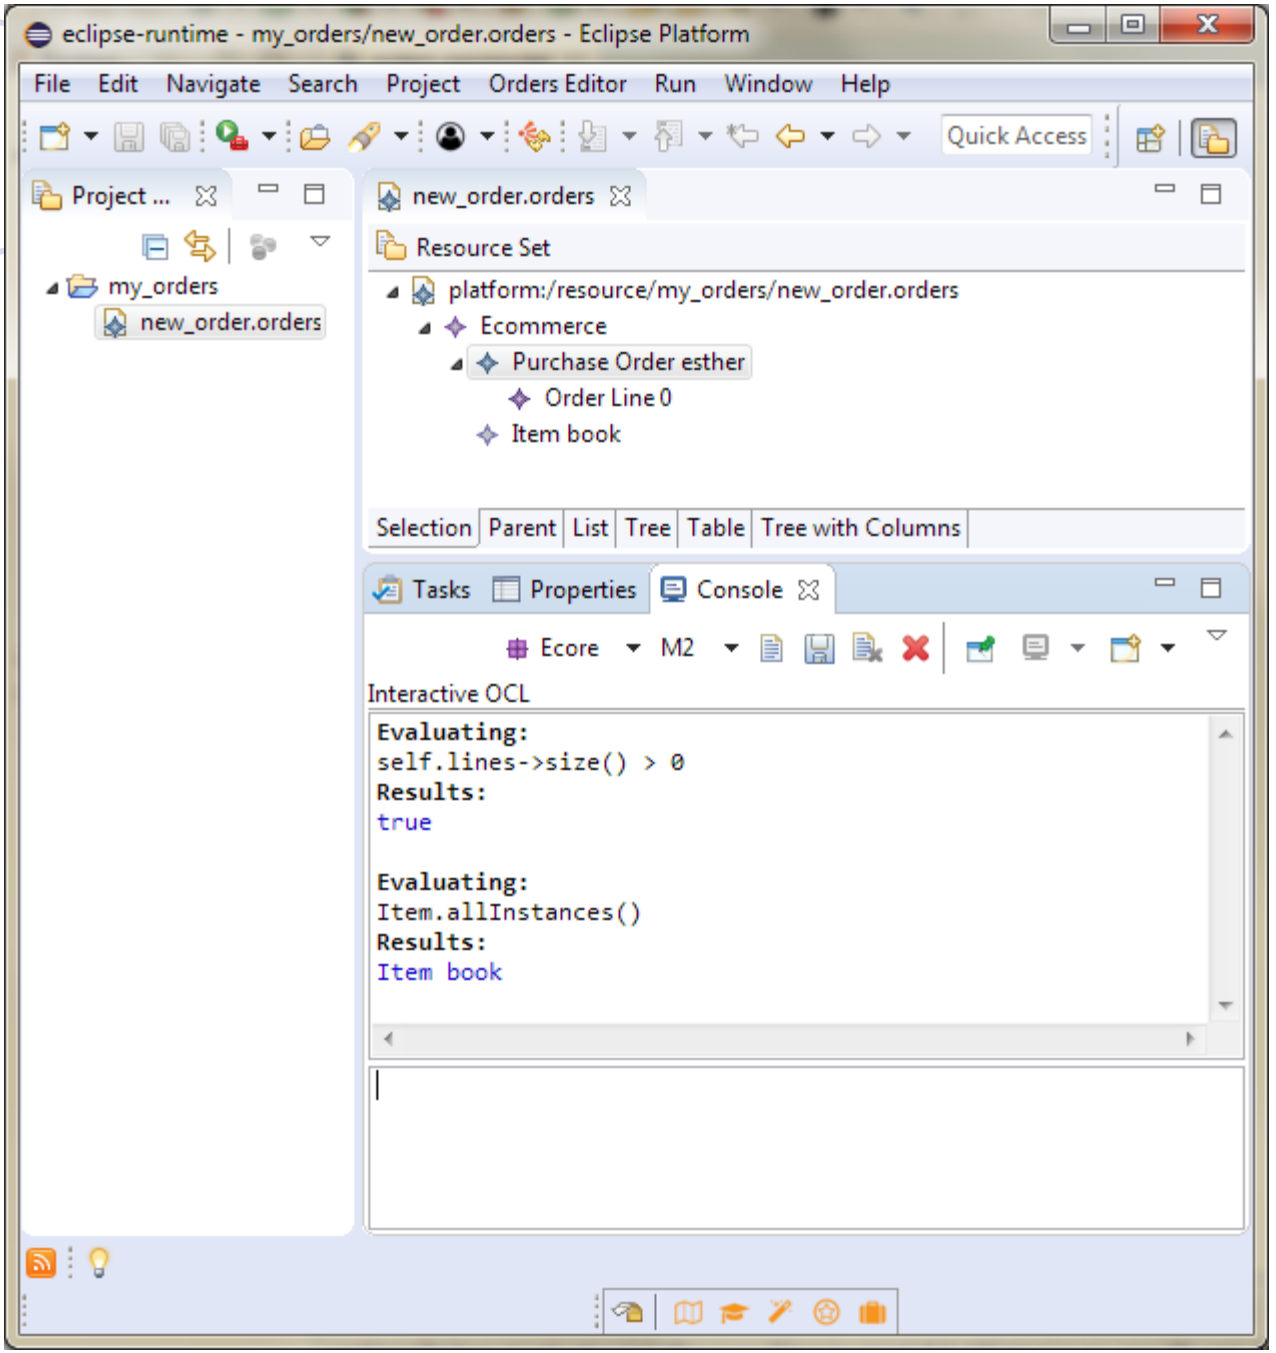


- Attributes and non-containment references can be edited in view *Properties*

- To validate an object, right-click on object, *Validate*
  - it validates the object, and the objetcs it contains (also indirectly)
  - errors are shown in a dialogbox, and in view *Problems*

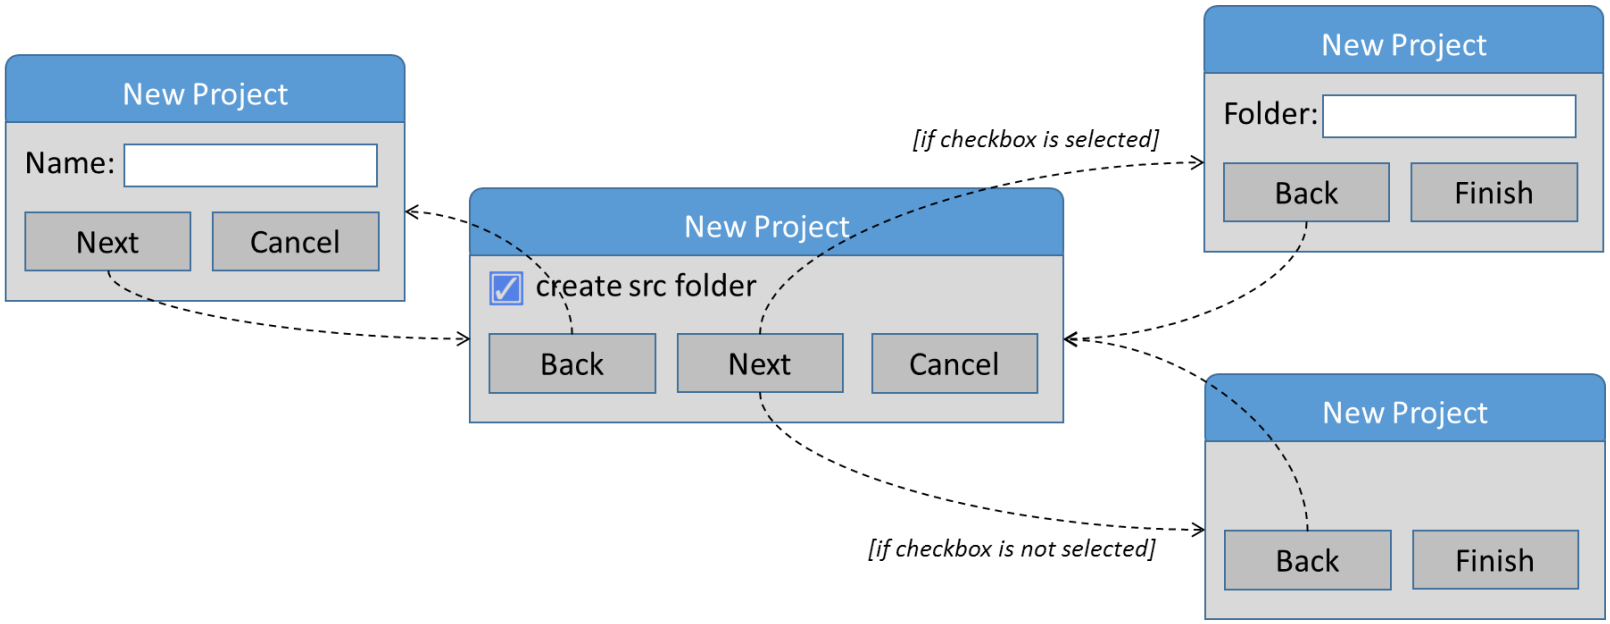
Interactive OCL console

- Right-click on a model element
- Select OCL / Show OCL Console



Exercise

- Build an EMF meta-model for defining wizards (the detailed list of requirements is published in moodle)
- Build the corresponding tree-like editor
- Build a model using the tree-like editor



Hand-in: October 26th (together with Xtext editor)

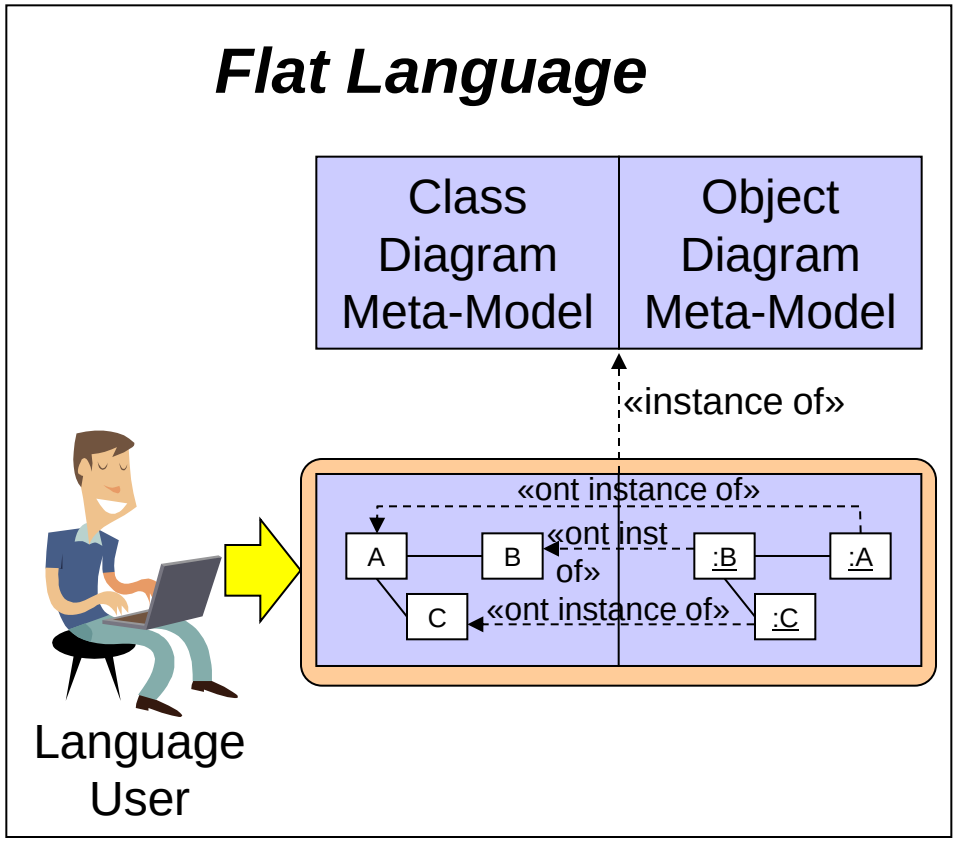
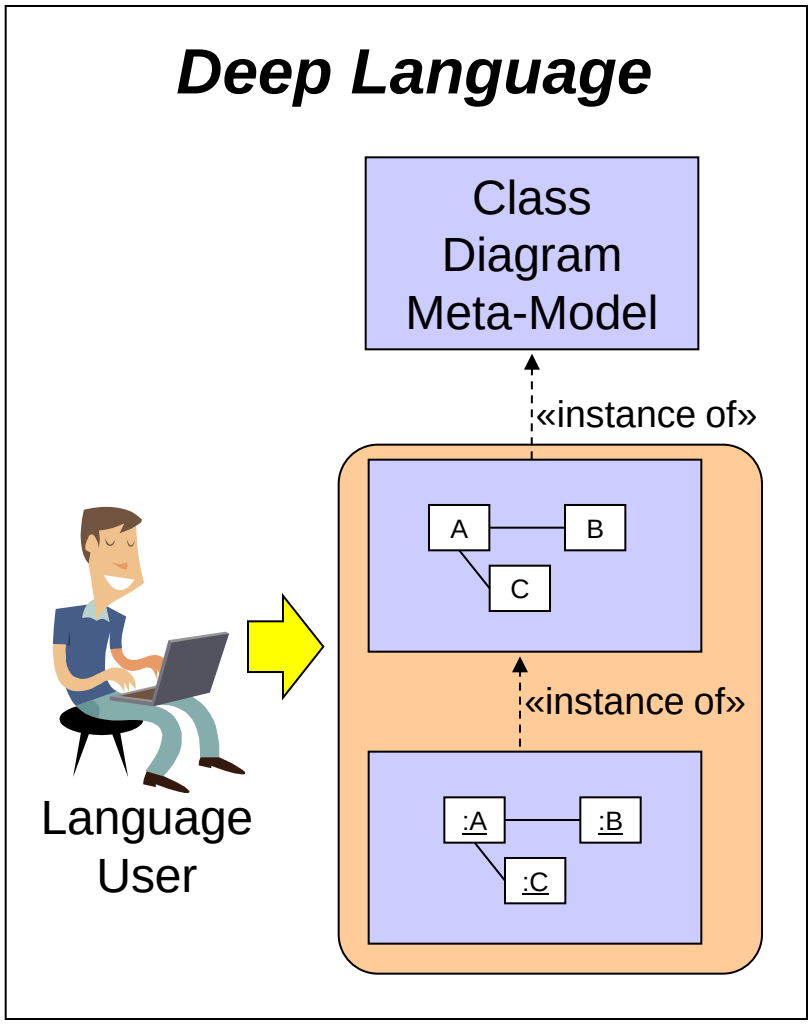
Rearchitecting the UML infrastructure



- In UML, both class and object diagrams are defined with a “big” meta-model.
- Both class and object diagrams are at the same meta-level.

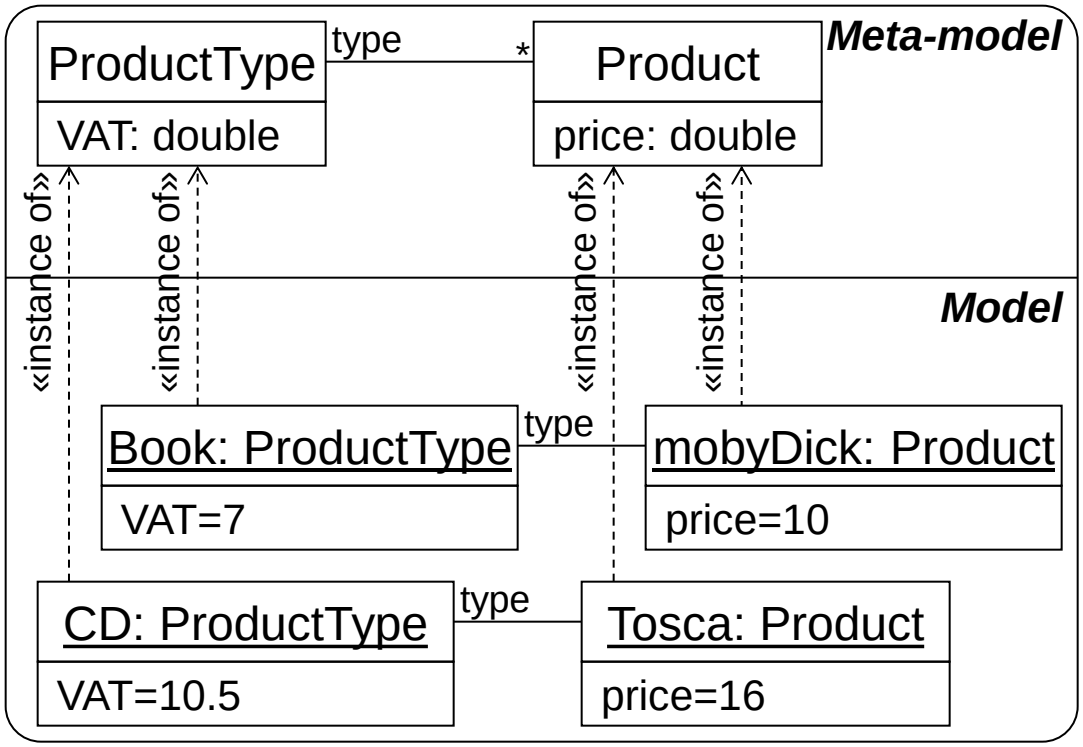
Rearchitecting the UML infrastructure



- We can use multi-level modelling to set object diagrams as instances of class diagrams.
- This way, we only need to define the meta-model of class diagrams at the top-level: object diagrams are instances of the class diagrams.
- We obtain a simpler description of the UML.

Multi-level meta-modelling

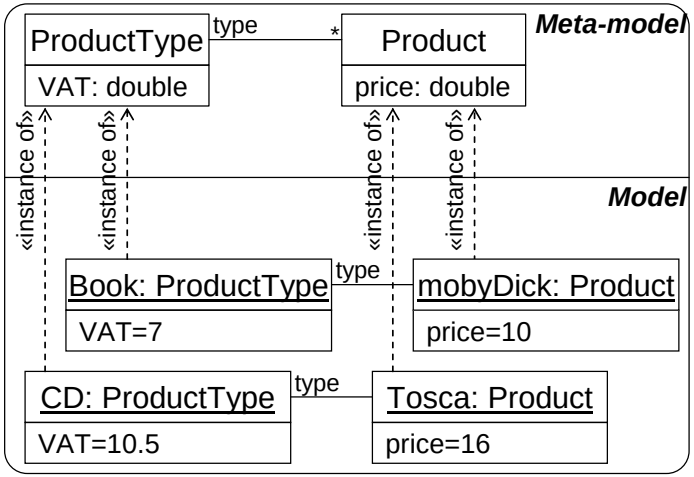
Let's consider the following system.



Typical example of the type-object pattern.

Multi-level meta-modelling

- Disadvantages:
  - The type relation is a kind of <<instance of>> relation, but the architecture does not provide support for it.
  - Manual maintenance of typing relations at the model level.

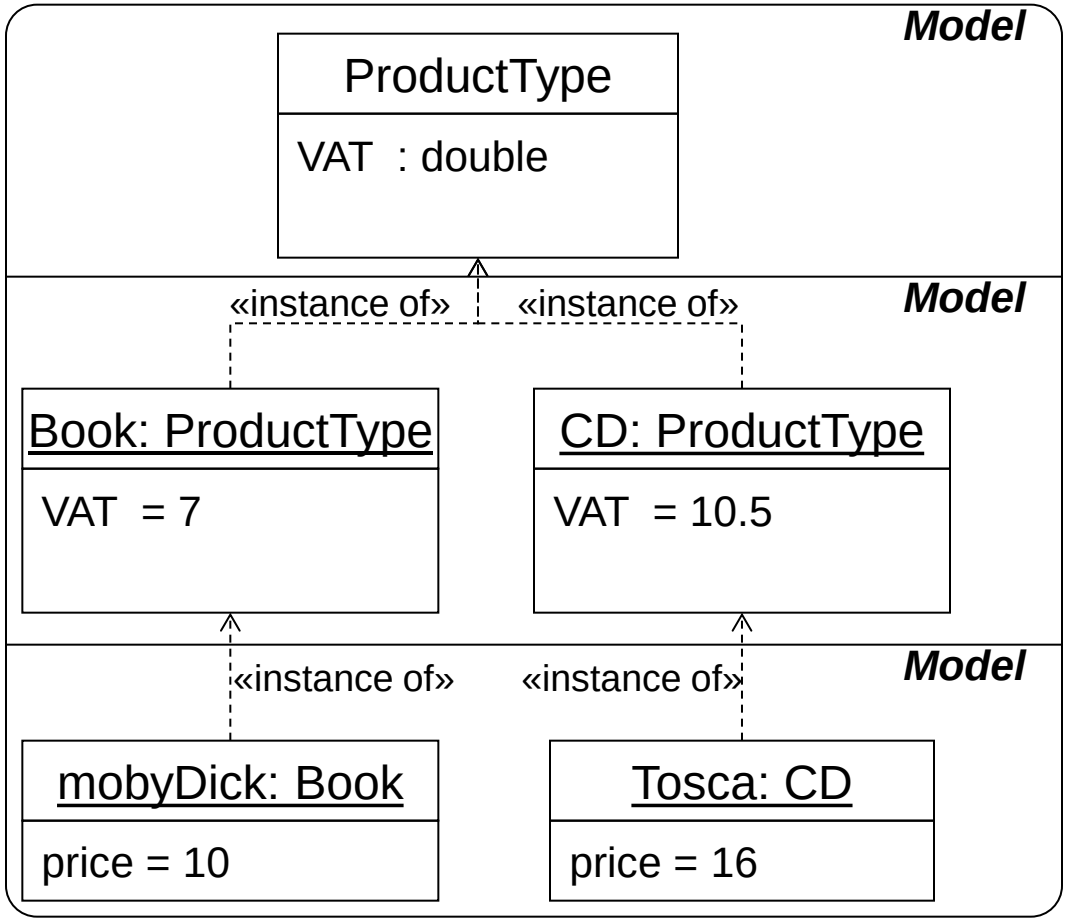


- Are three meta-levels shoehorned in two?

- This is not the only case: UML class/object diagrams, web languages (type nodes/nodes, user types/users, etc).

Multi-level meta-modelling

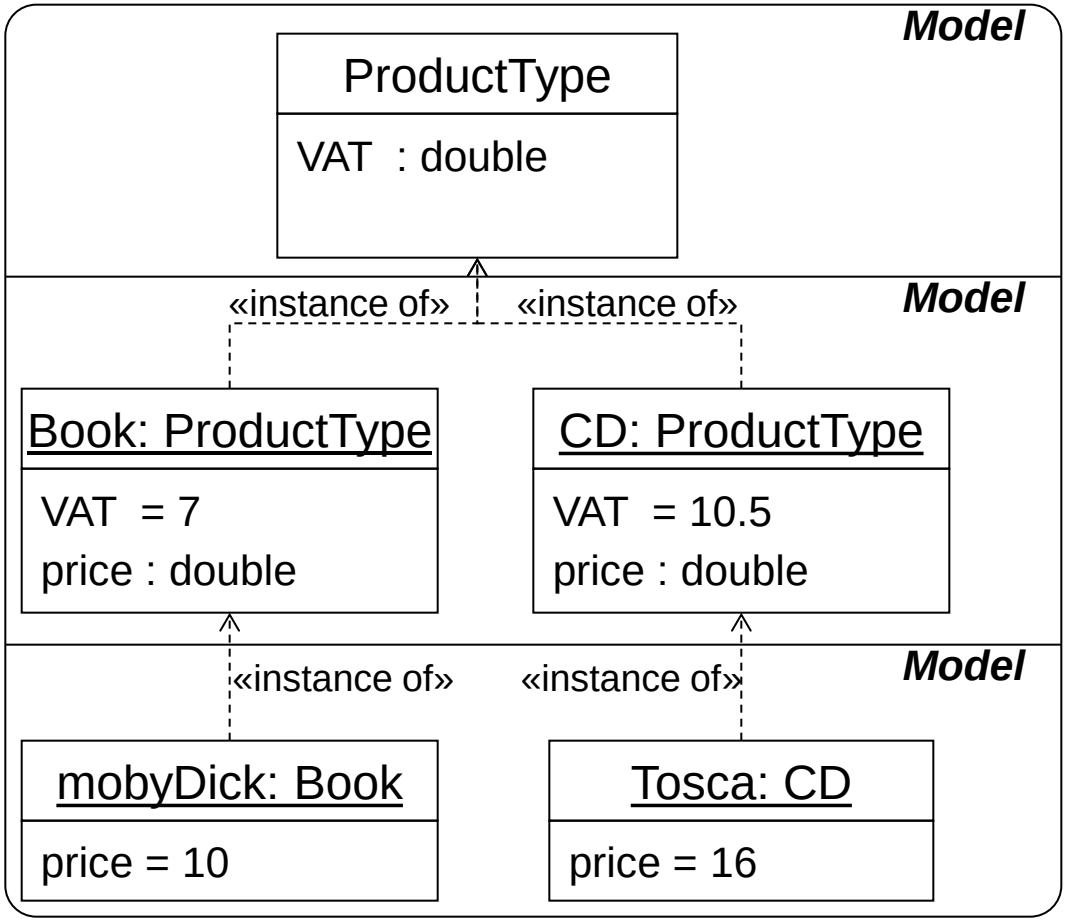
We can organise the system in 3 levels:



Multi-level meta-modelling

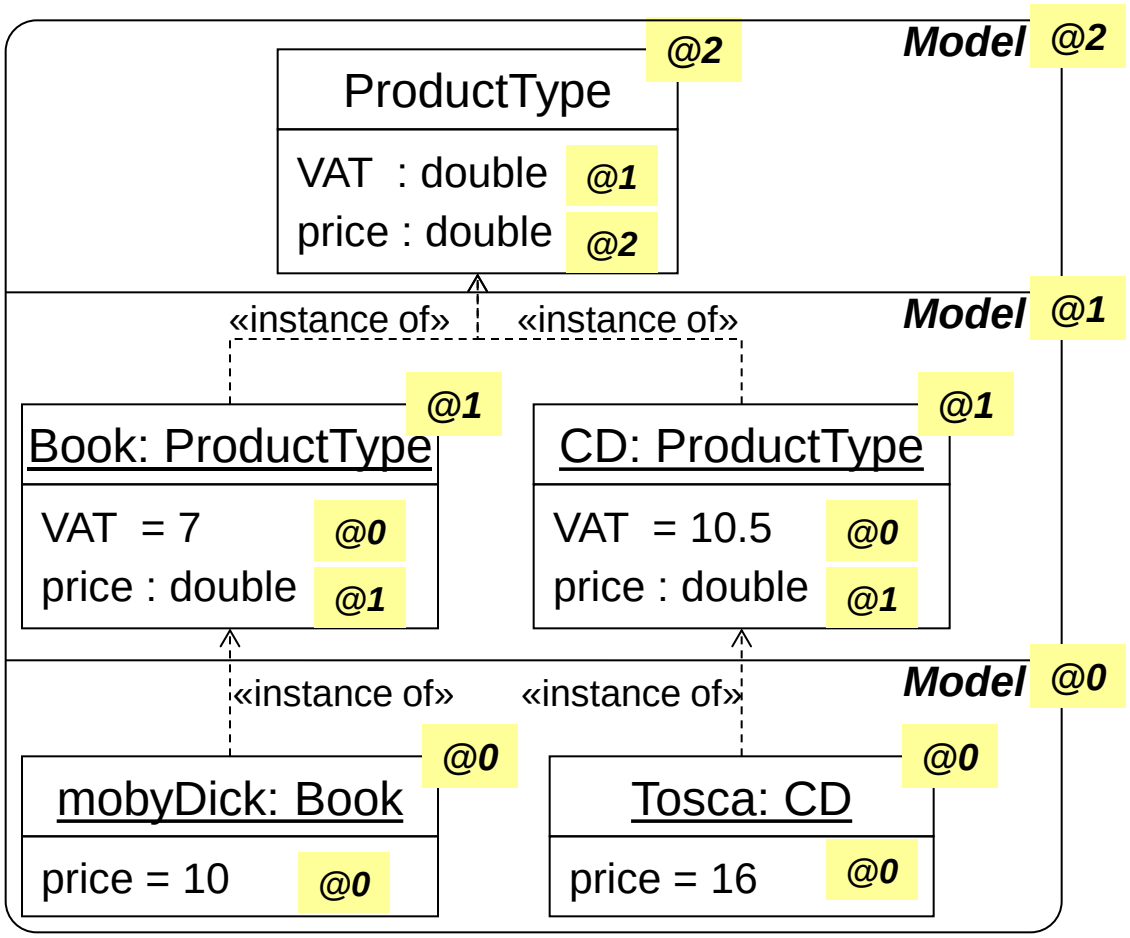
Clabjects

Elements with both type (class) and object (object) facets.



Multi-level meta-modelling

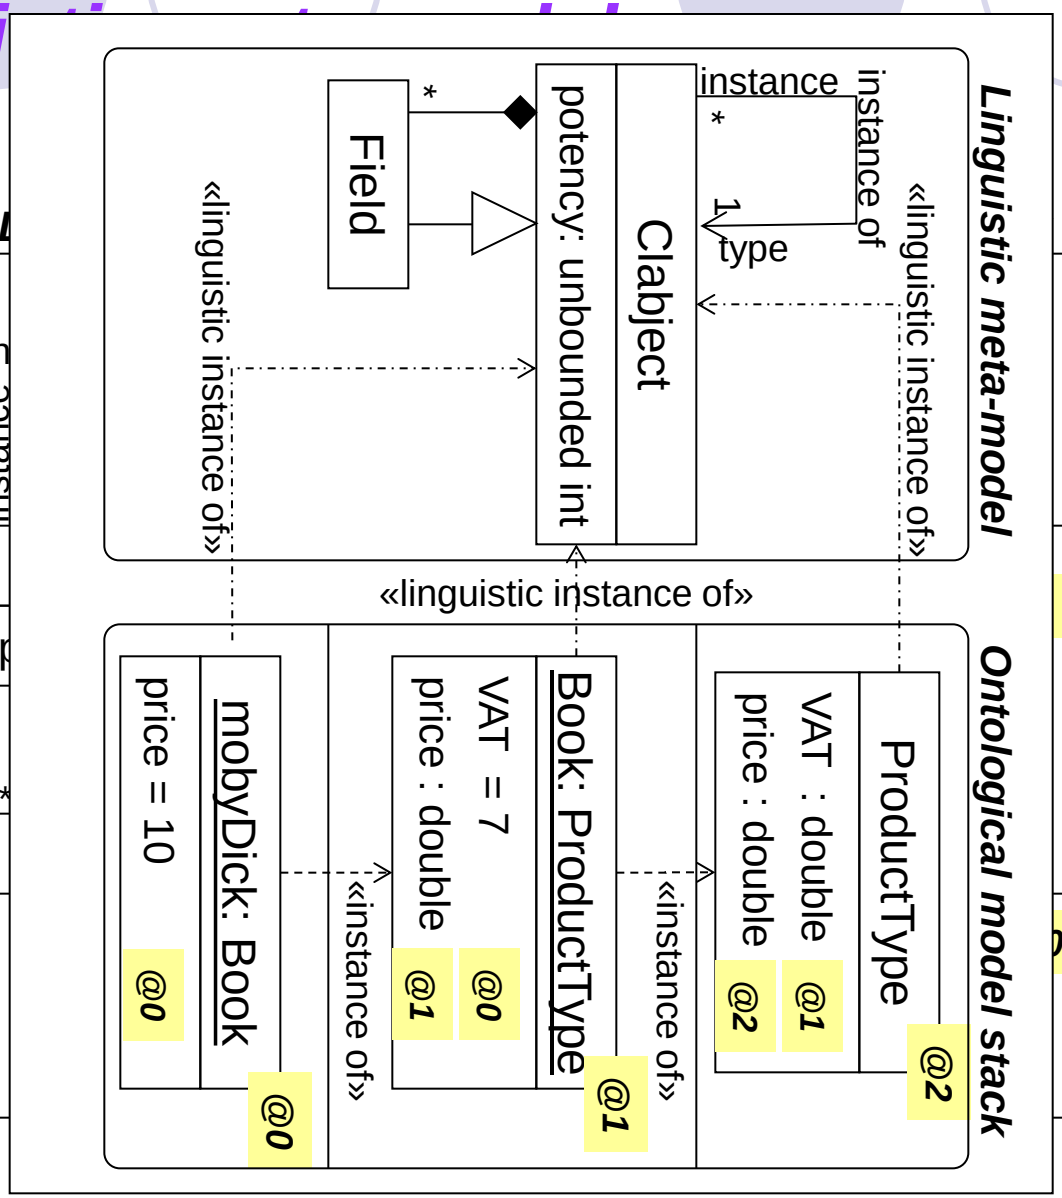
Deep characterisation: potency



Atkinson, C., Kühne, T.: Rearchitecting the UML infrastructure. ACM Trans. Model. Comput. Simul. 12(4), 290–321 (2002)

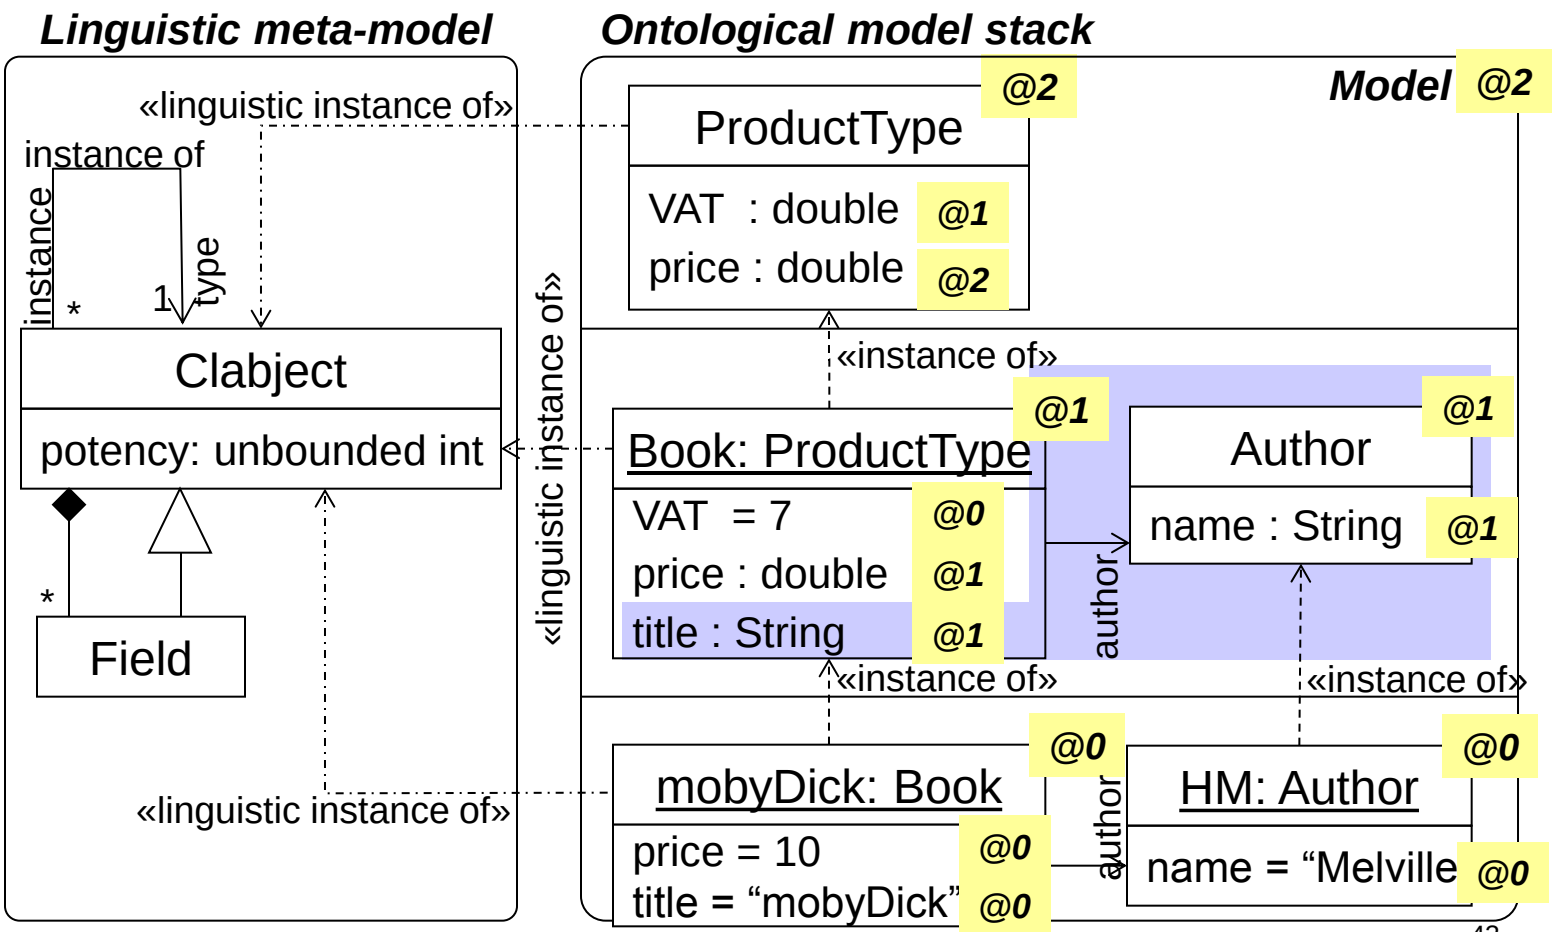
Multi-level meta-modelling

Linguistic meta-modelling



Multi-level meta-modelling

Linguistic extension



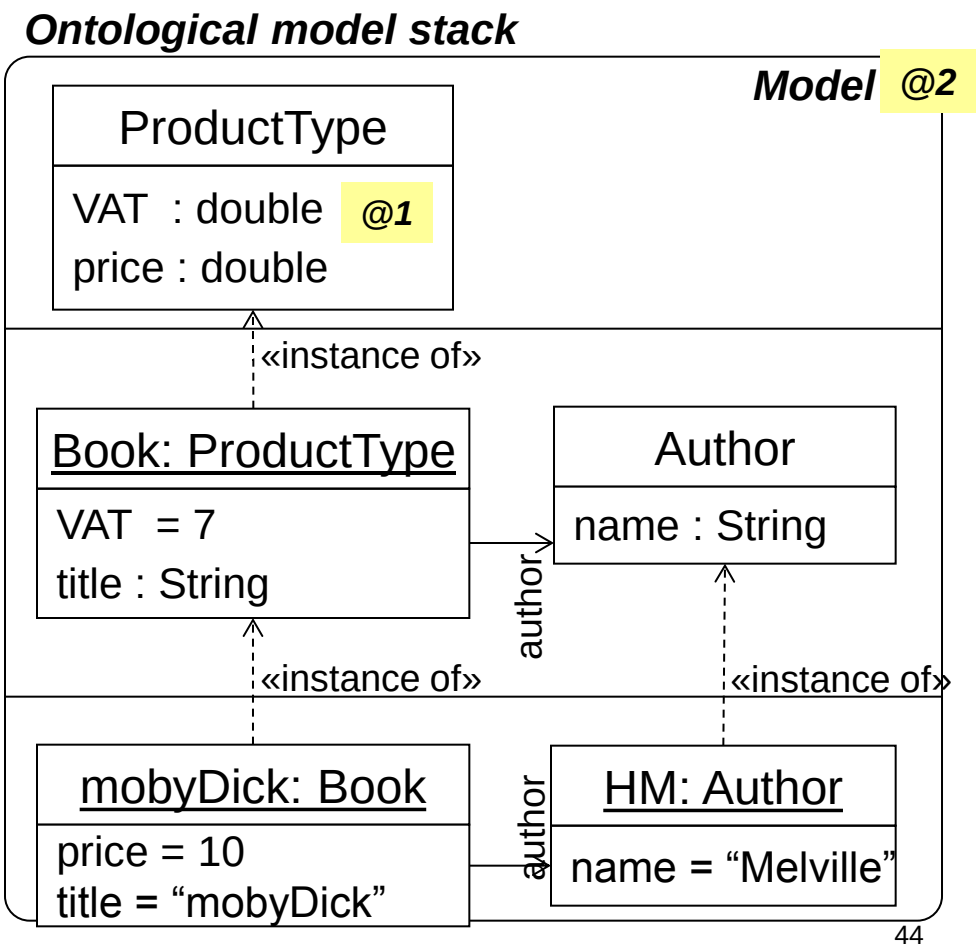
Multi-level meta-modelling

metaDepth: http://metadepth.org/

```
Model Store@2{
  Node ProductType{
    VAT@1 : double = 7.5;
    price : double = 10;
  }
}

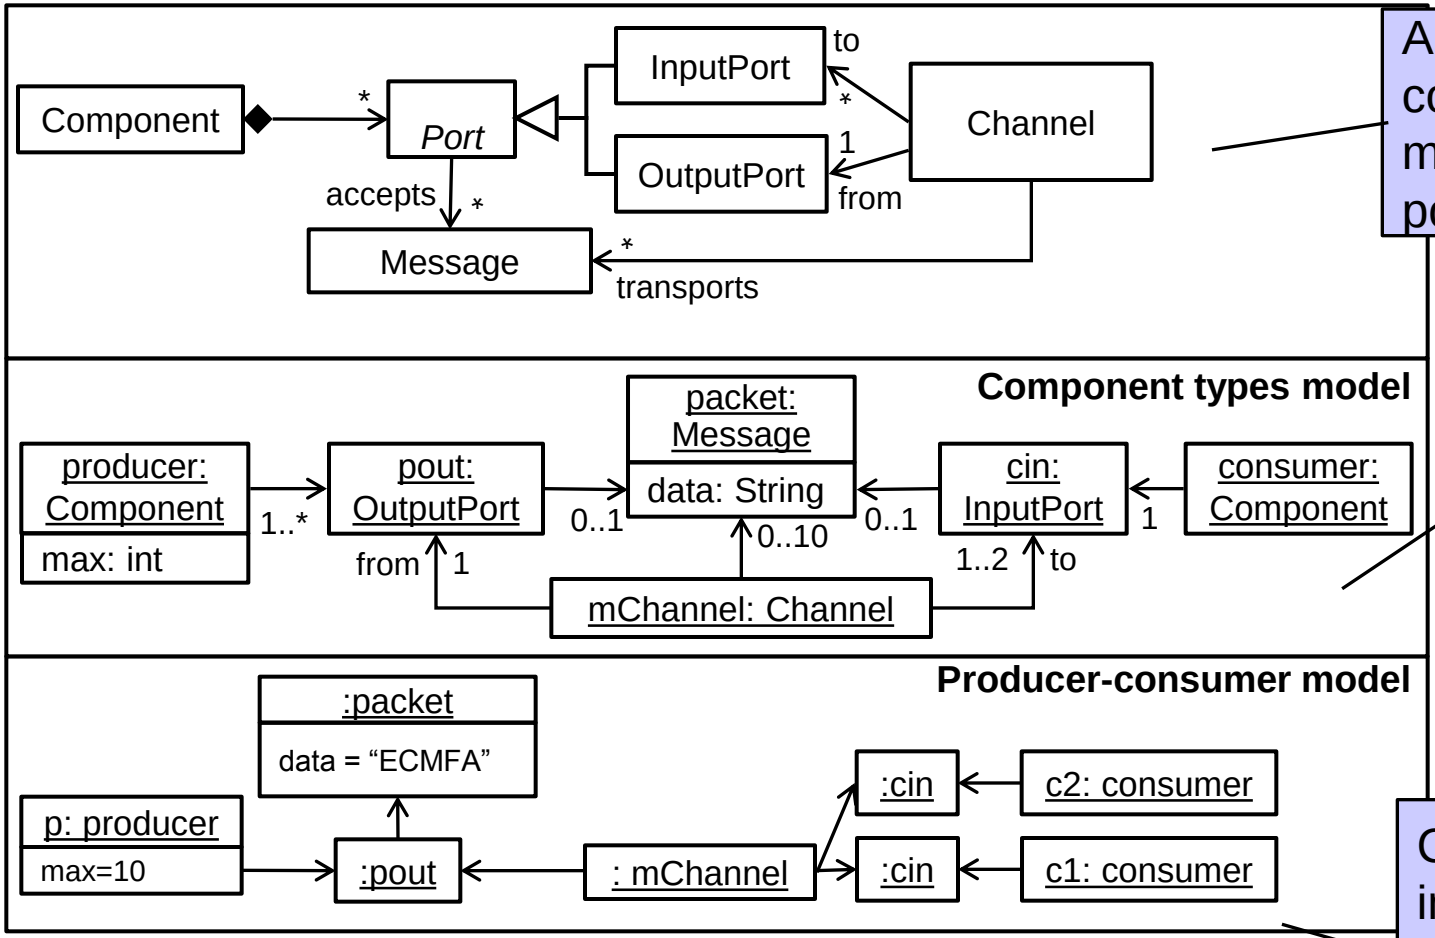
Store Library{
  ProductType Book{
    VAT    = 7;
    title  : String;
    author : Author;
  }
  Node Author{
    name : String;
  }
}

Library MyLibrary{
  Book mobyDick{
    price  = 10;
    title = "mobyDick";
    author = HM;
  }
  Author HM{
    name = "Herman Melville";
  }
}
```



Multi-level meta-modelling

Example: component-based modelling



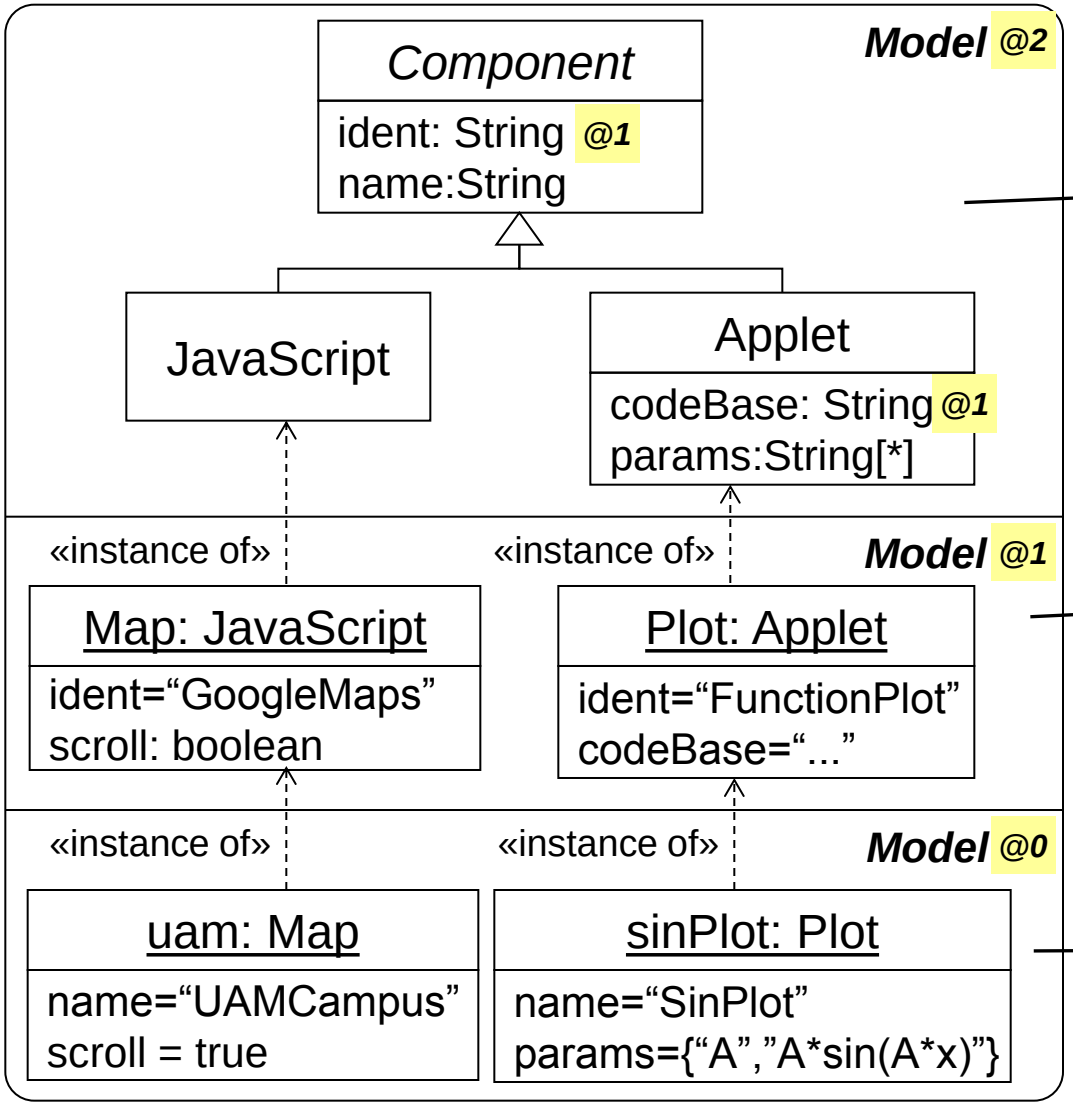
A language to define component types, message types, ports, channels.

Several component and message types can be defined. Ports may have a cardinality.

Components can be instantiated, with the number of ports conforming to the cardinality.

Multi-level meta-modelling

Example: web components



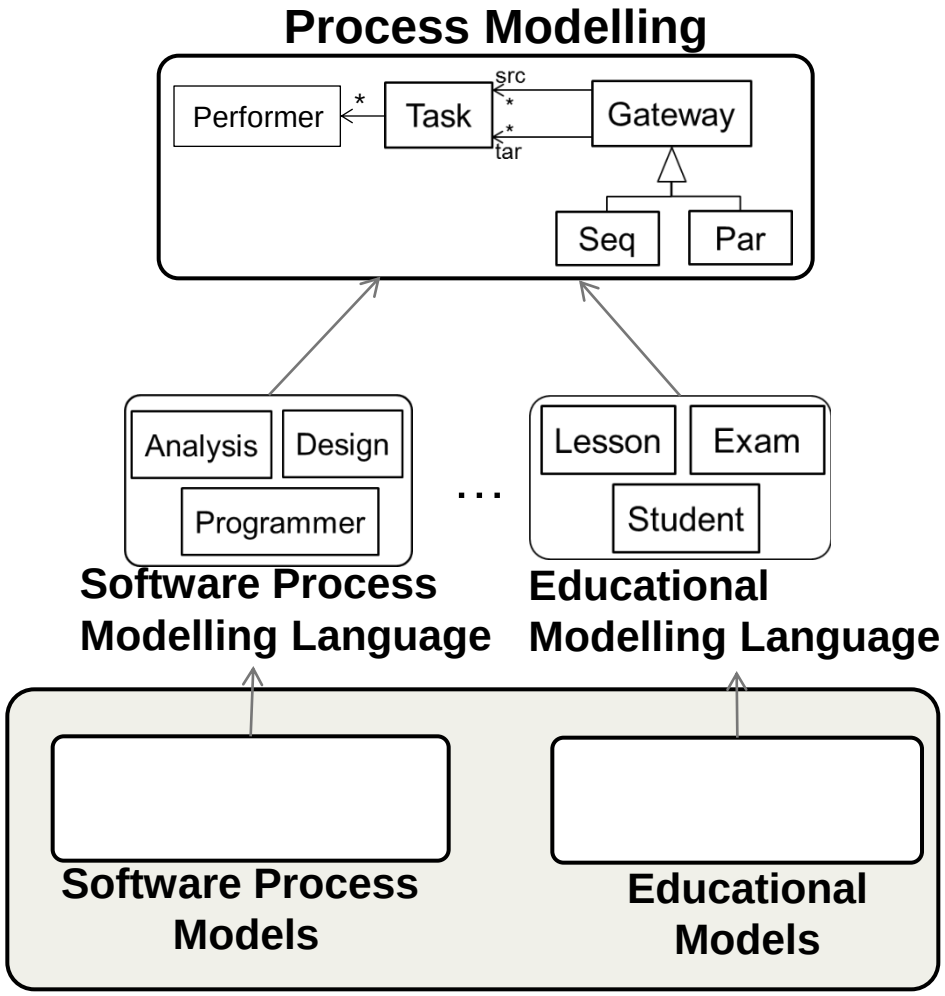
A language to define components for different web technologies

A library of components

Construction of mashup-like applications by interconnecting component instances

Multi-level meta-modelling

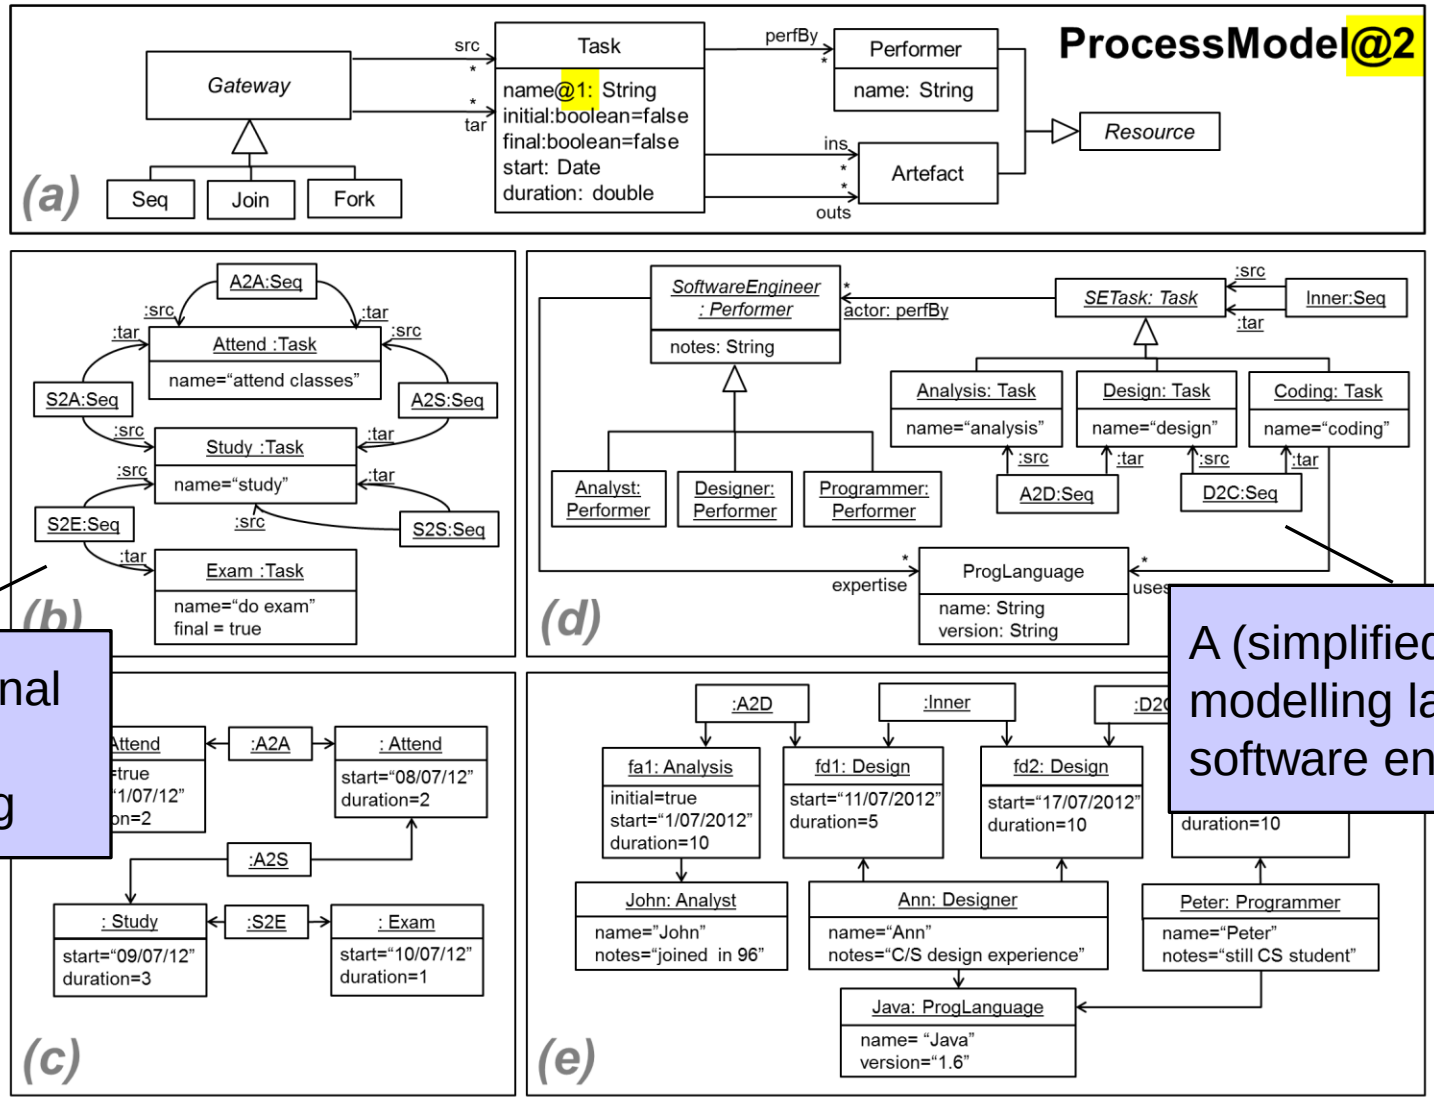
Families of modelling languages



- We can use multi-level modelling to define families of related modelling languages.
- A top-level meta-model for process modelling, which can be used to define specialized languages for process modelling in: software engineering, education, logistics, production engineering, etc.

Multi-level meta-modelling

Families of modelling languages



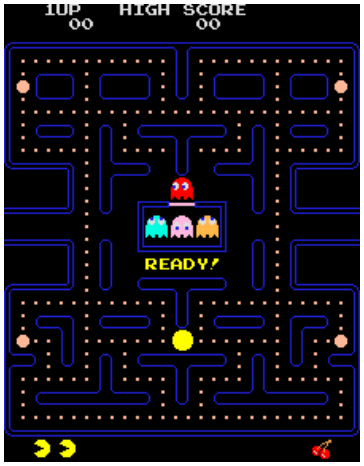
Educational process modelling

A (simplified) process modelling language for software engineering

Multi-level meta-modelling

Exercise: arcade/adventure games

Sabre Wulf



Pacman

Commando

Atic atac

Gauntlet

Multi-level meta-modelling

Exercise: arcade/adventure games

- Create a language to describe adventure games (like Pacman, Sabre Wulf, Gauntlet, Atic-atac, etc.)
- Games based on connected tiles, which are able to hold treasures and characters
  - Heroes (like Pacman)
  - Evils (like Ghosts)
- Heroes have an initial number of lives; while at run-time, they hold an actual number of lives and a score
- The language should permit creating types of tiles, heroes, evils and treasures (with custom properties)
- The language should permit describing the initial game configuration

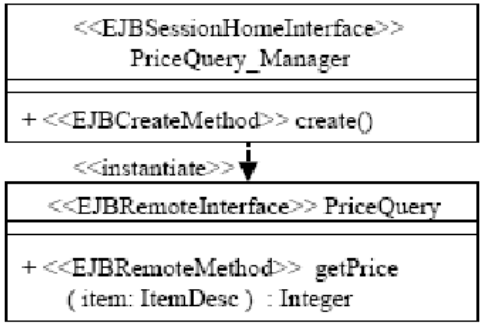
- Introduction
- Two-level meta-modelling
- Multi-level meta-modelling
- **Profiles**

- Graph grammars
- Bibliography

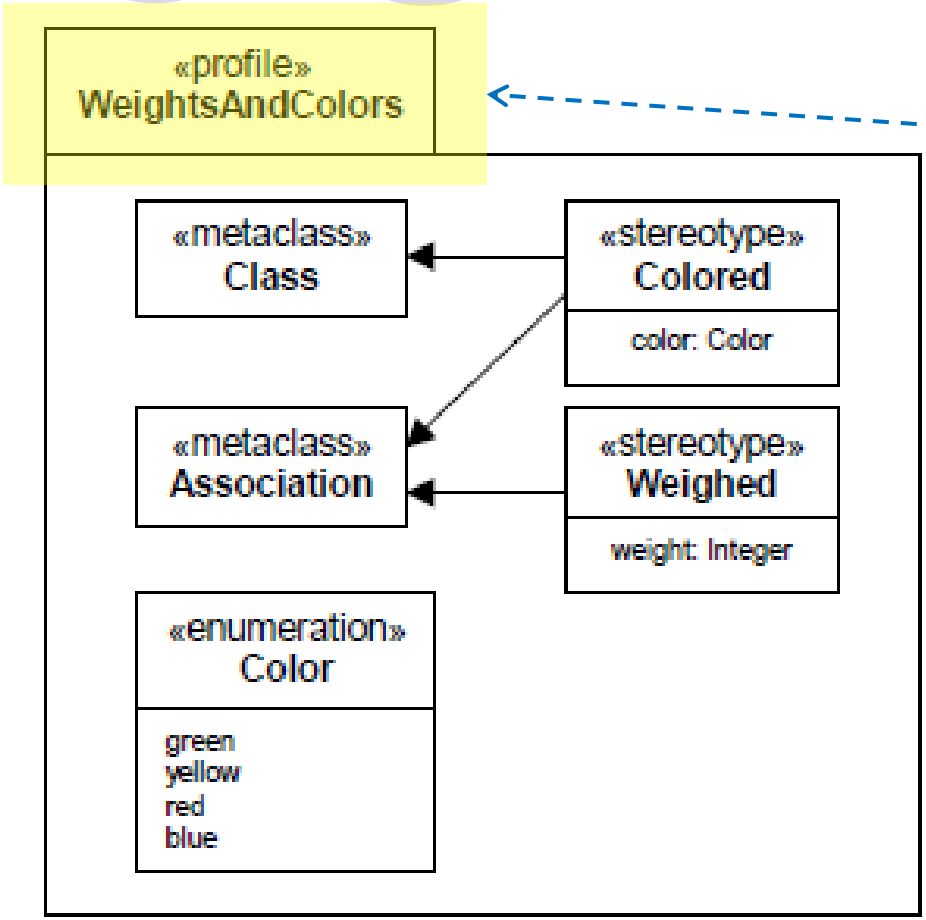
UML Profiles

- **Extension** mechanism to declare new constructions in UML, adapted to a specific domain.
- They define specialised meta-models for a domain, as a subset of the UML meta-model.
- A profile is defined by means of:
  - stereotypes, e.g. <<JavaClass>> in the EJB profile
  - constraints attached to the stereotype, expressed in OCL
  - tagged values (meta-attributes) attached to the stereotype
- Some examples: EJBs, Web Services, SysML, CORBA, MARTE…



UML Profiles

Defining a profile

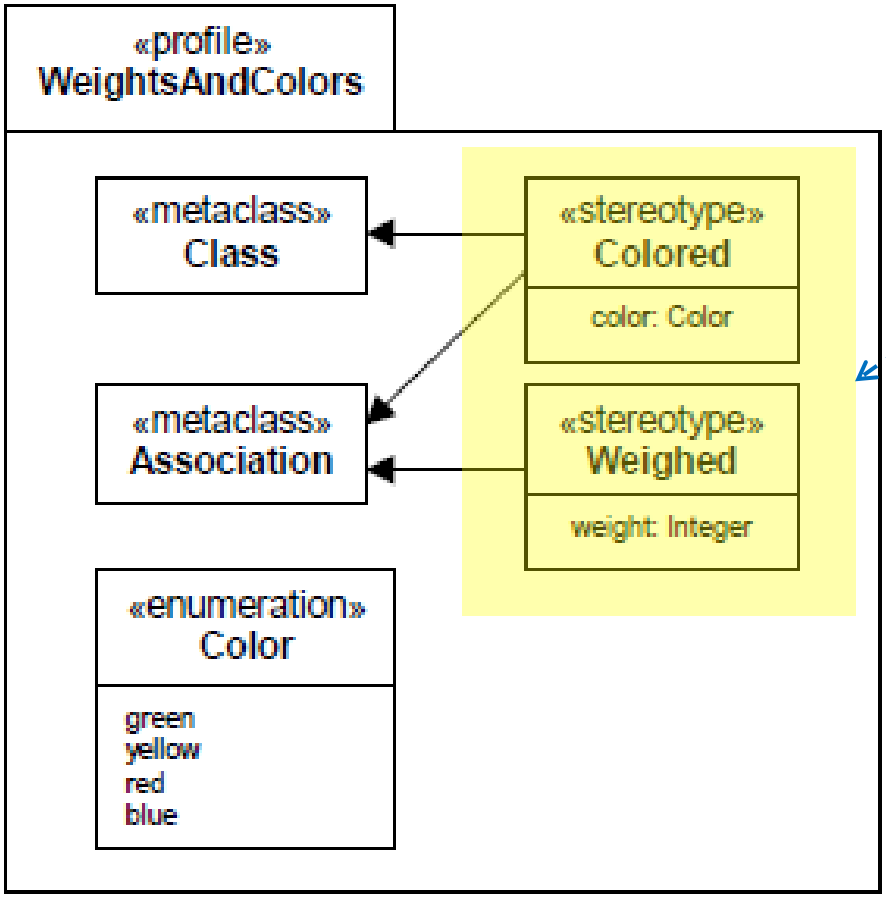


A profile is defined in a UML package with the stereotype <<profile>>.

```
context UML::InfrastructureLibrary::Core::Constructs::Association
  inv :     self.isStereotyped("Colored") implies
      self.connection->forAll(isStereotyped("Colored") implies color=self.color)
```

UML Profiles

Defining a profile



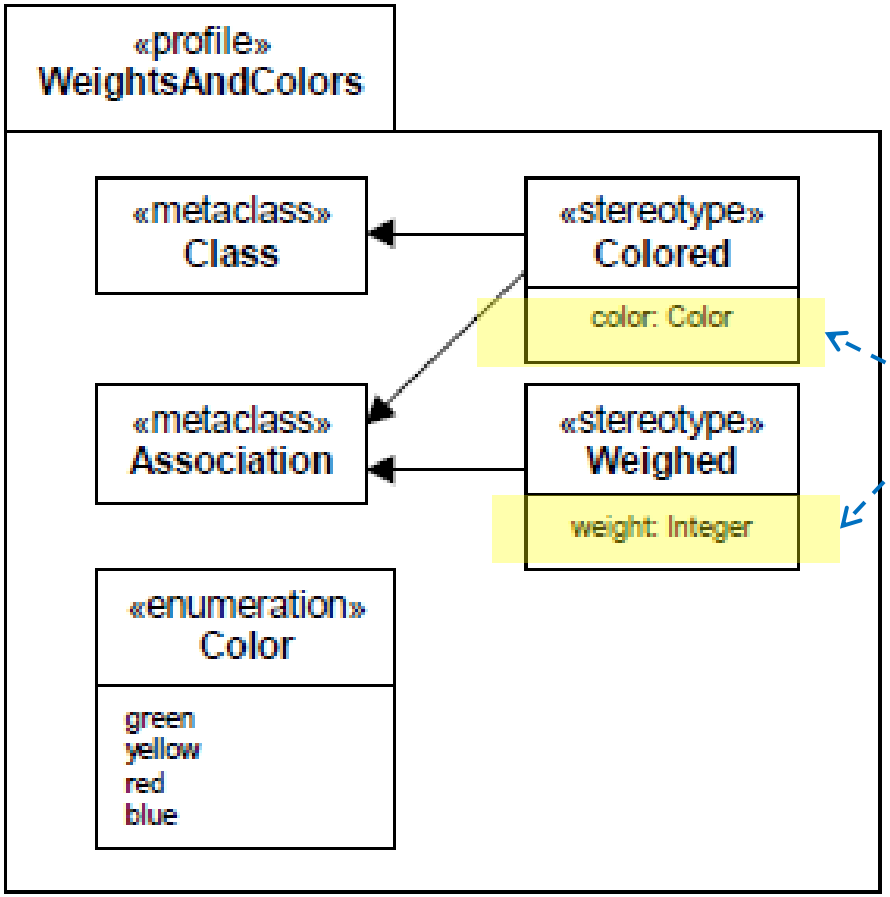
Stereotypes represent domain concepts.

They have a name, and point to the UML meta-model elements for which we are defining the stereotype.

```
context UML::InfrastructureLibrary::Core::Constructs::Association
  inv :     self.isStereotyped("Colored") implies
      self.connection->forAll(isStereotyped("Colored") implies color=self.color)
```

UML Profiles

Defining a profile



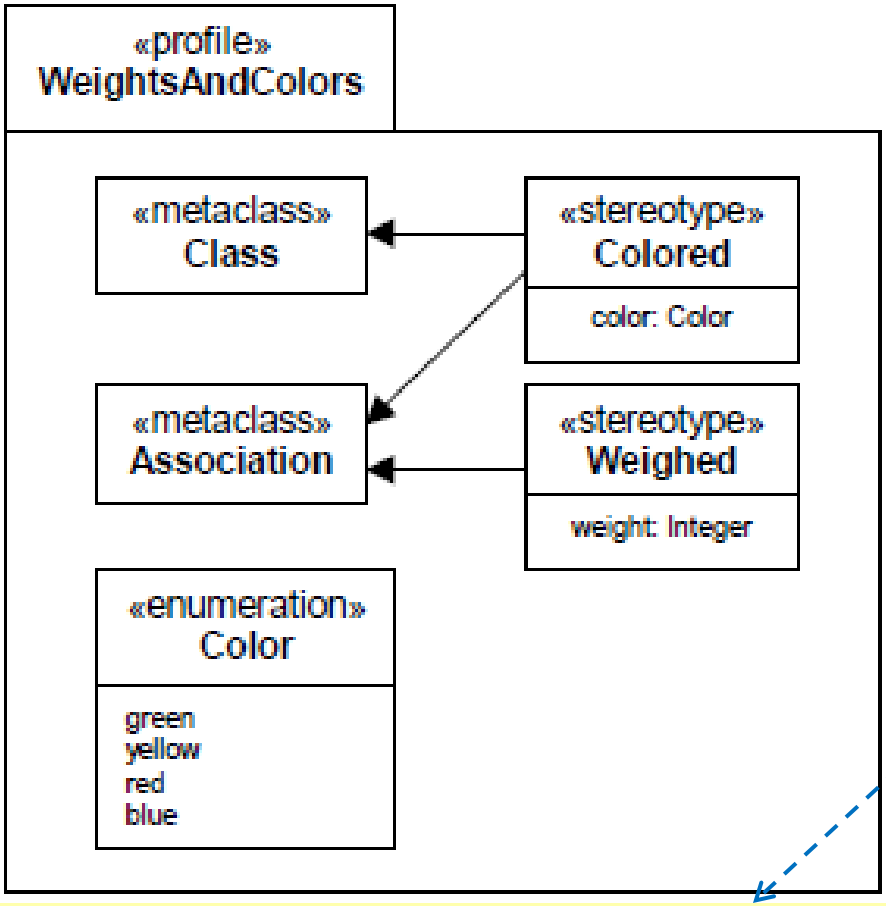
Tagged values are meta-attributes for the elements tagged by the stereotype.

They have name and type.

```
context UML::InfrastructureLibrary::Core::Constructs::Association
  inv :     self.isStereotyped("Colored") implies
      self.connection->forAll(isStereotyped("Colored") implies color=self.color)
```

UML Profiles

Defining a profile



We can define constraints for the stereotyped elements, either in OCL or in natural language.

```
context UML::InfrastructureLibrary::Core::Constructs::Association
  inv :     self.isStereotyped("Colored") implies
      self.connection->forAll(isStereotyped("Colored") implies color=self.color)
```

UML Profiles

Using a profile

Graph transformation

- Models are graphs.
- A (multi-)graph can be defined as G=(N, E, s, t), where is a set of nodes, E is a set of edges, and con s, t:E→N define the source and target nodes of edges.
- Nodes and edges can be typed, attributed.
- Formal techniques to manipulate graphs.
- Rules with left (LHS) and right hand side (RHS), both containing a graph.
- If there is an occurrence of the LHS in the host graph, we can substitute the occurrence by the RHS.

Graph transformation

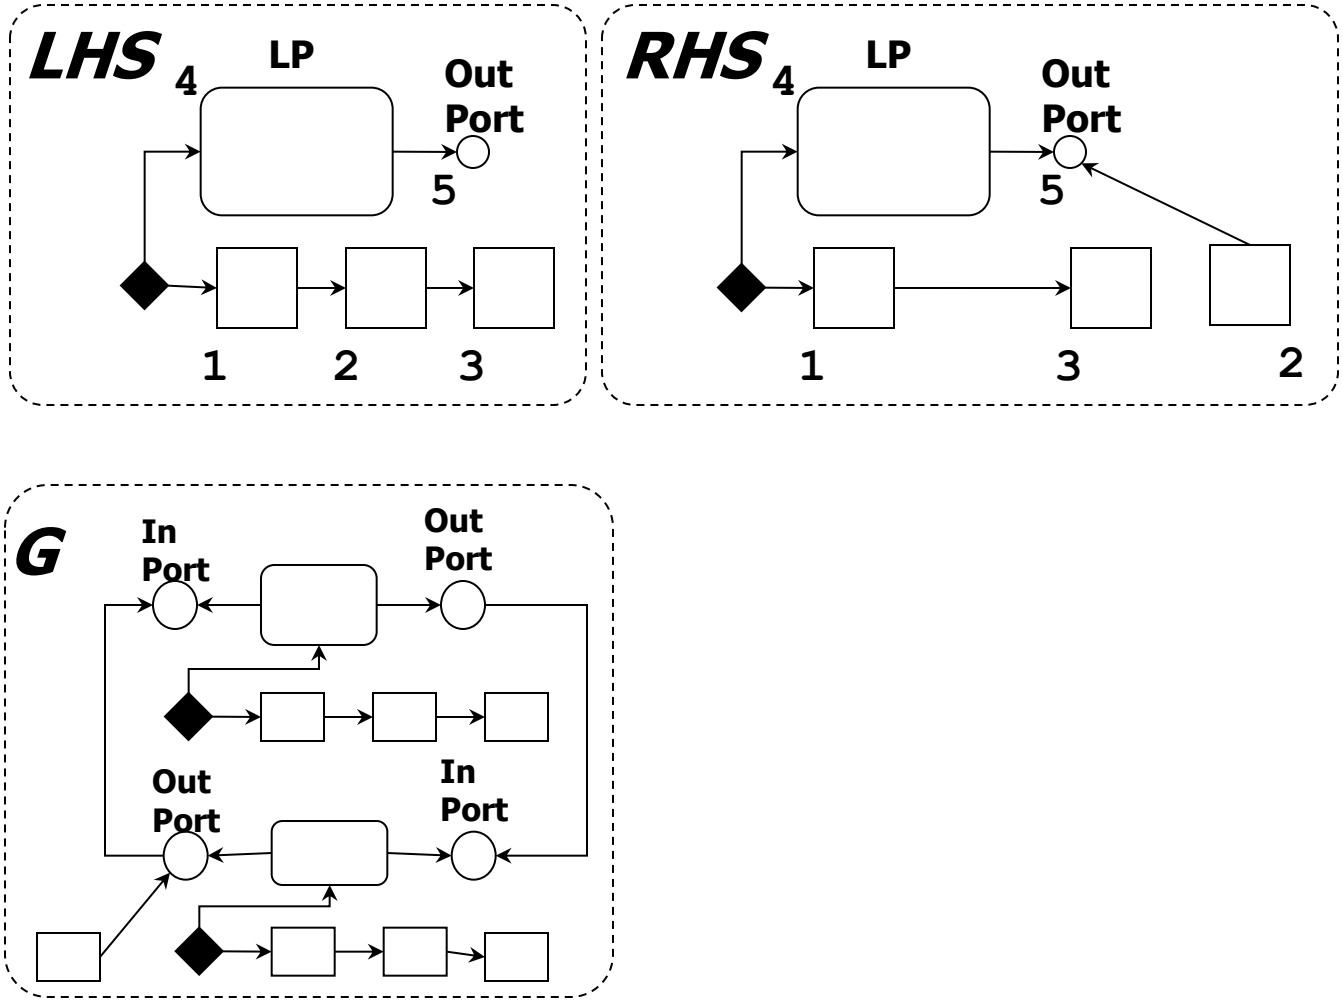
- Advantages: Visual, formal, declarative technique to express graph manipulations.

- Formal technique:
  - Based on category theory.
  - Analysis:
    - Termination (partially).
    - Confluence.
    - Dependencies/Conflicts/Concurrency between rules.

- Disadvantages:
  - Expressive power of rules (multi-objects, etc.)?
  - Execution control flow?

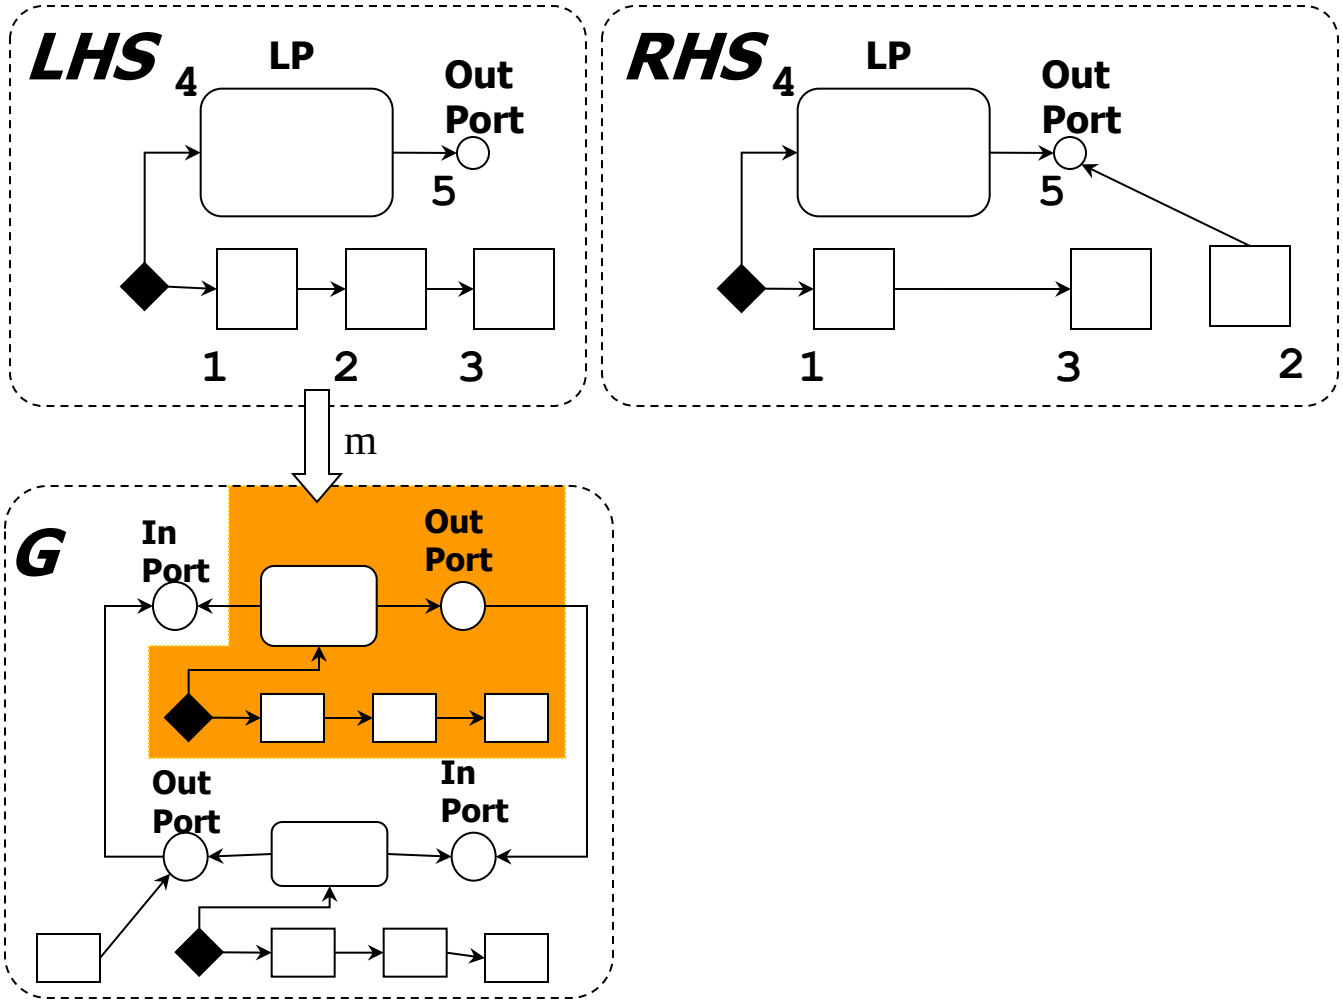
Graph transformation

Example



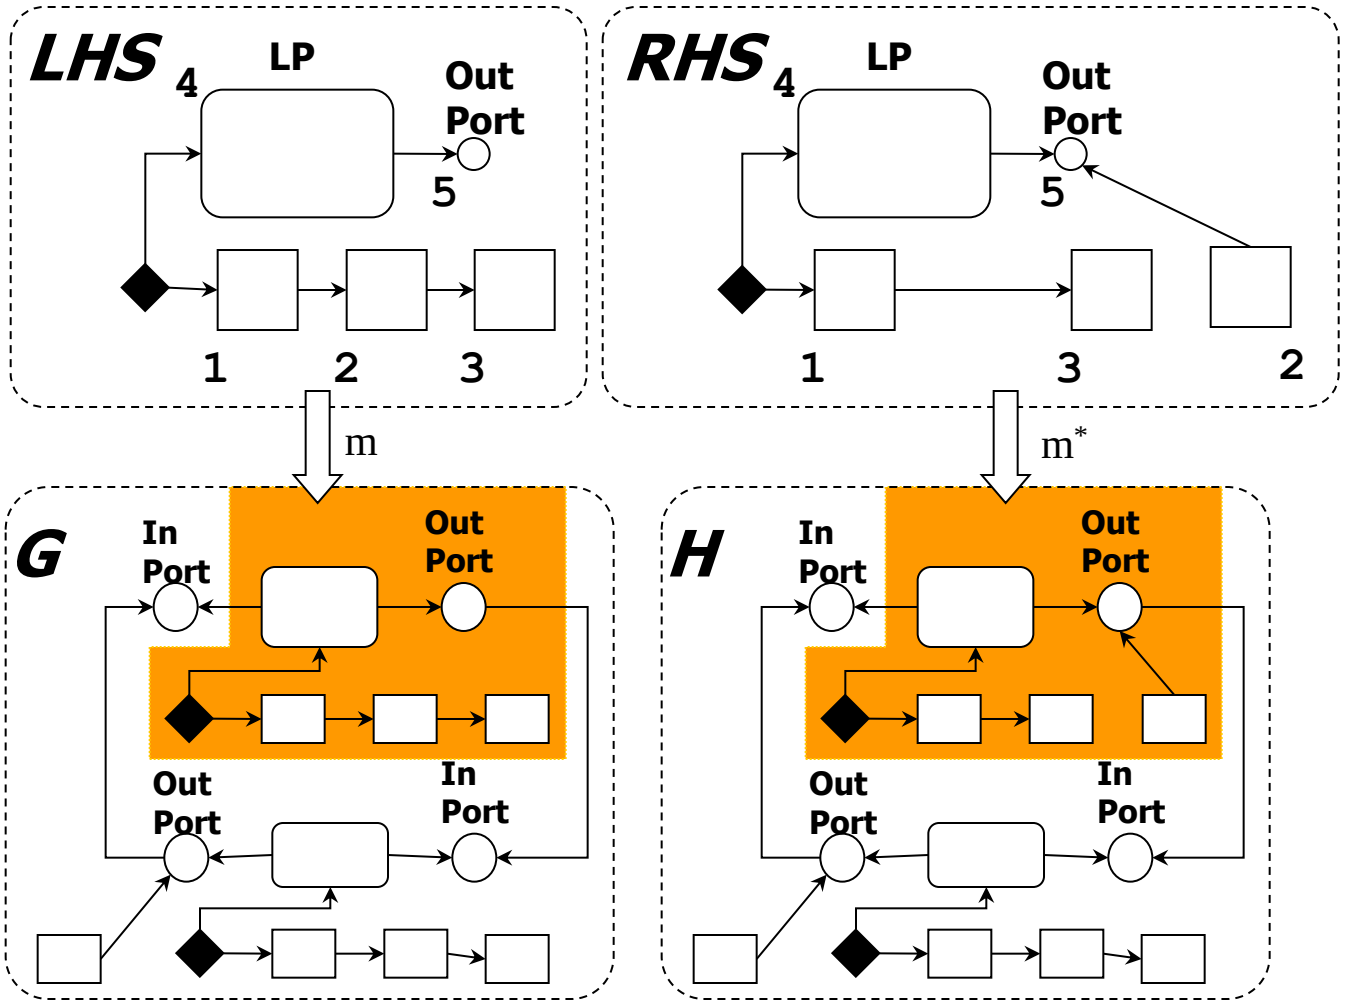
Graph transformation

Example



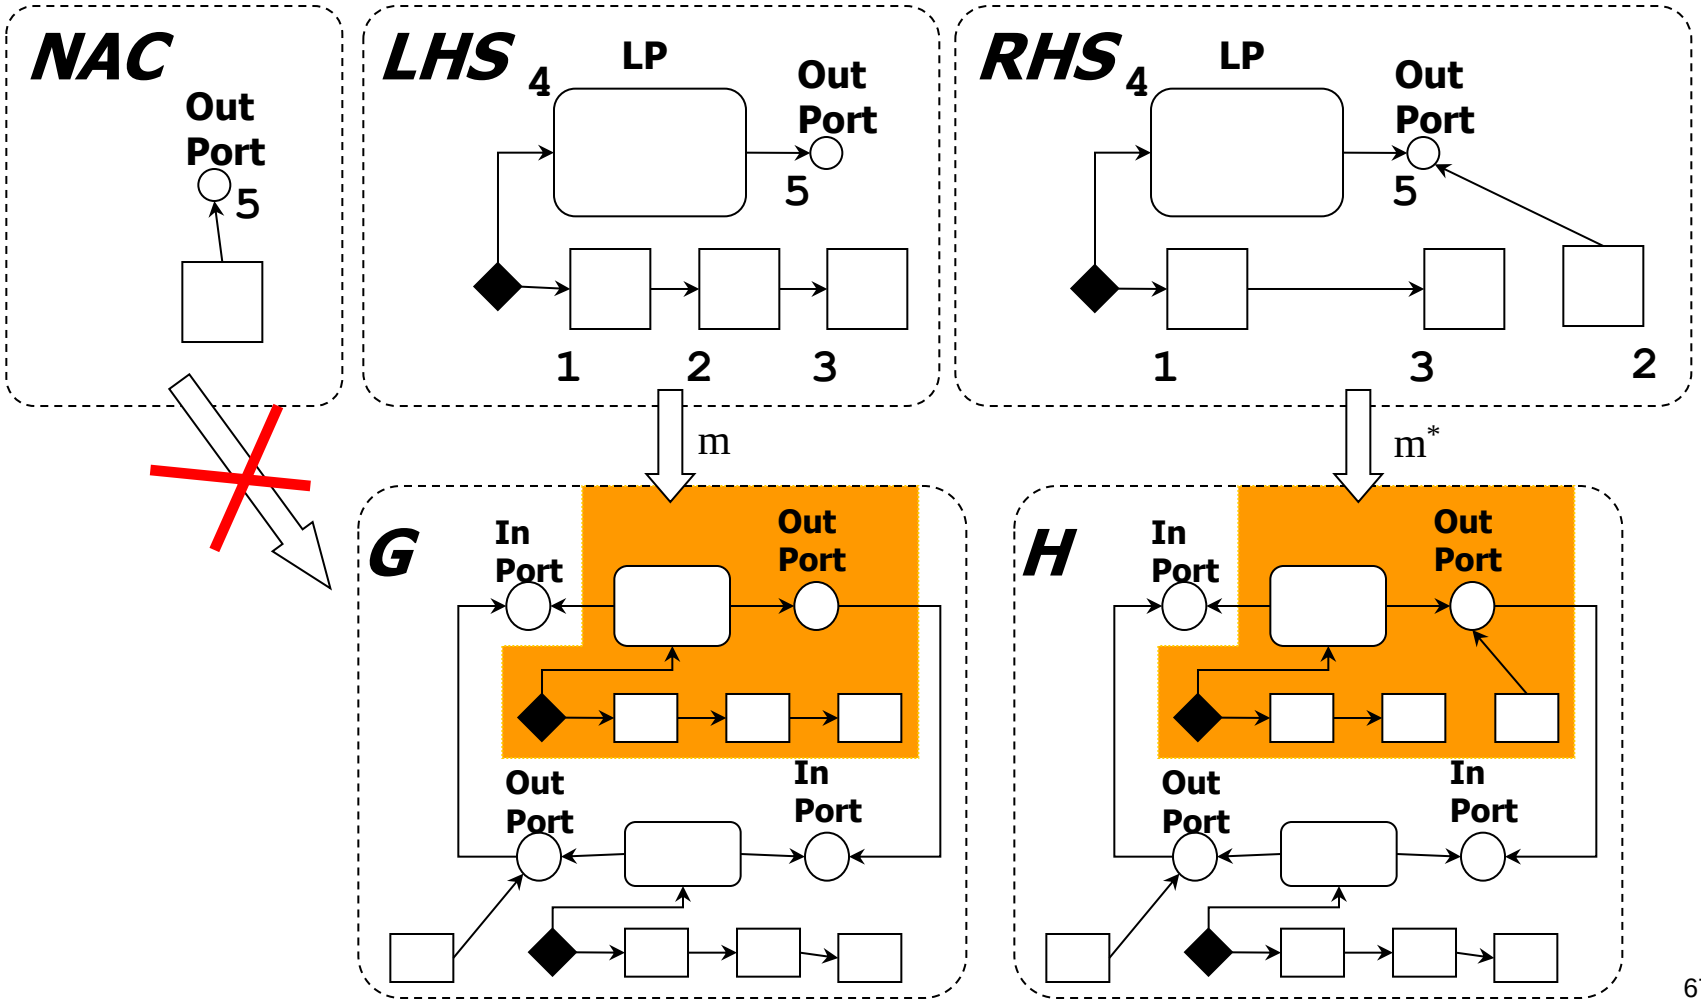
Graph transformation

Example



Graph transformation

Example, Negative Application Conditions



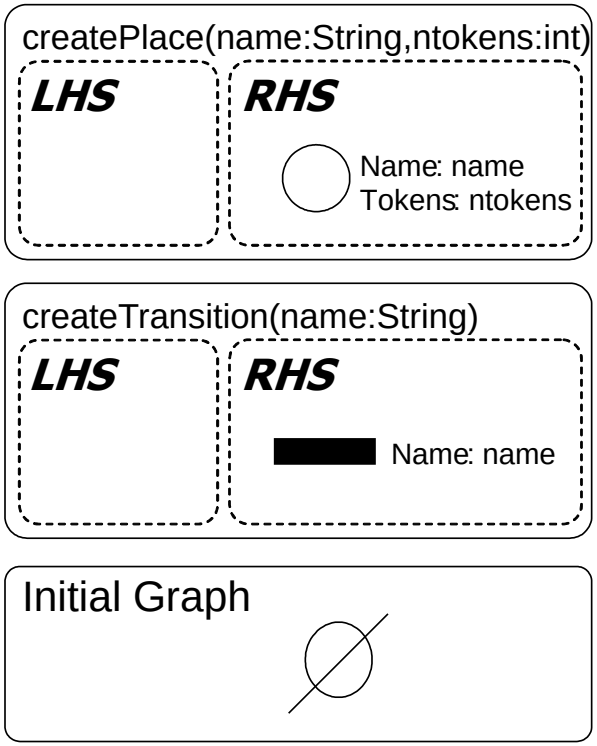
Graph transformation

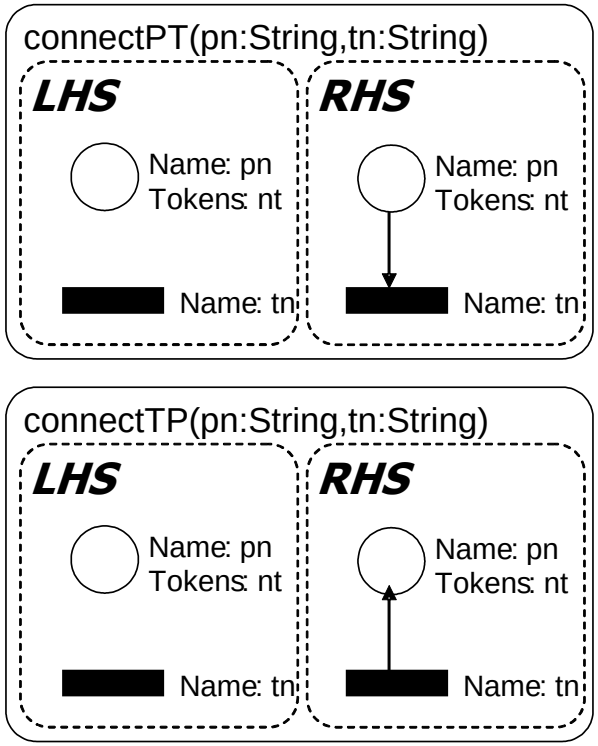
Creation grammars

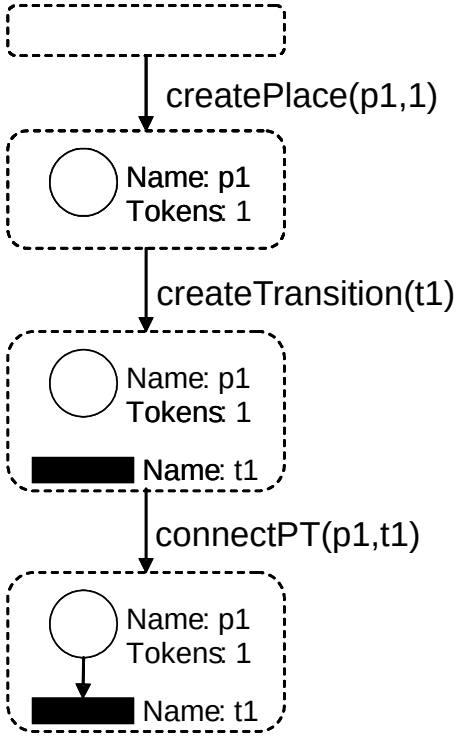
- A graph grammar consists of a set of rules and an initial graph: $GG=\{\{p_1,\ldots,p_n\}, G_0\}$.
- A grammar describes a language: The grammar semantics are all graphs that can be derived by applying the grammar rules in 0 or more steps.
- Do we need additional constraints (like we use OCL in meta-modelling)?
  - Application conditions for rules.
  - Graph constraints.

Graph transformation

Example, Petri nets



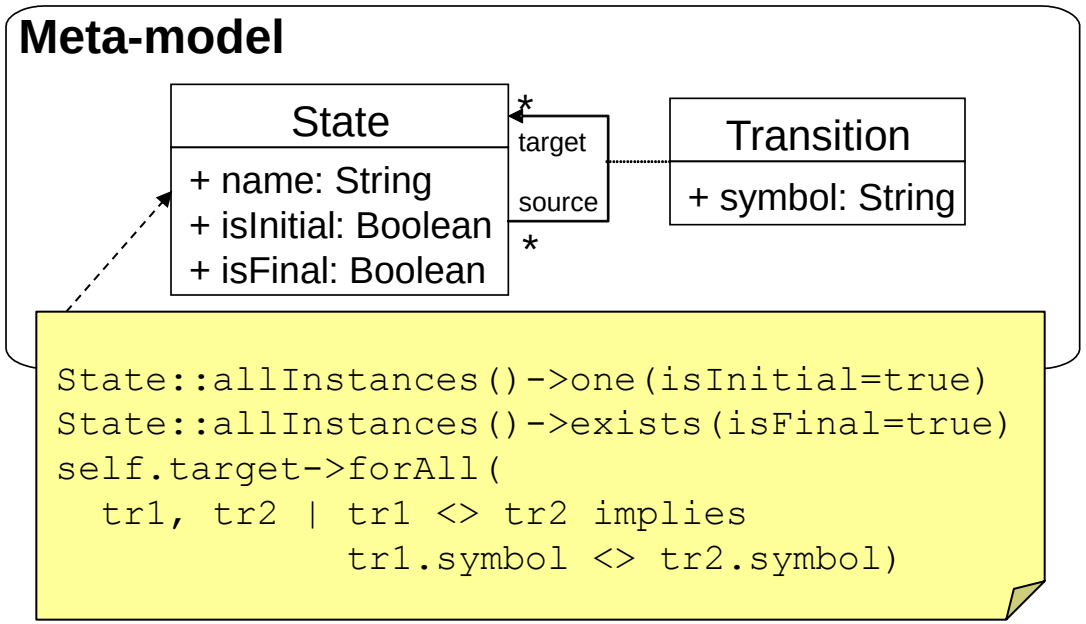




Graph transformation

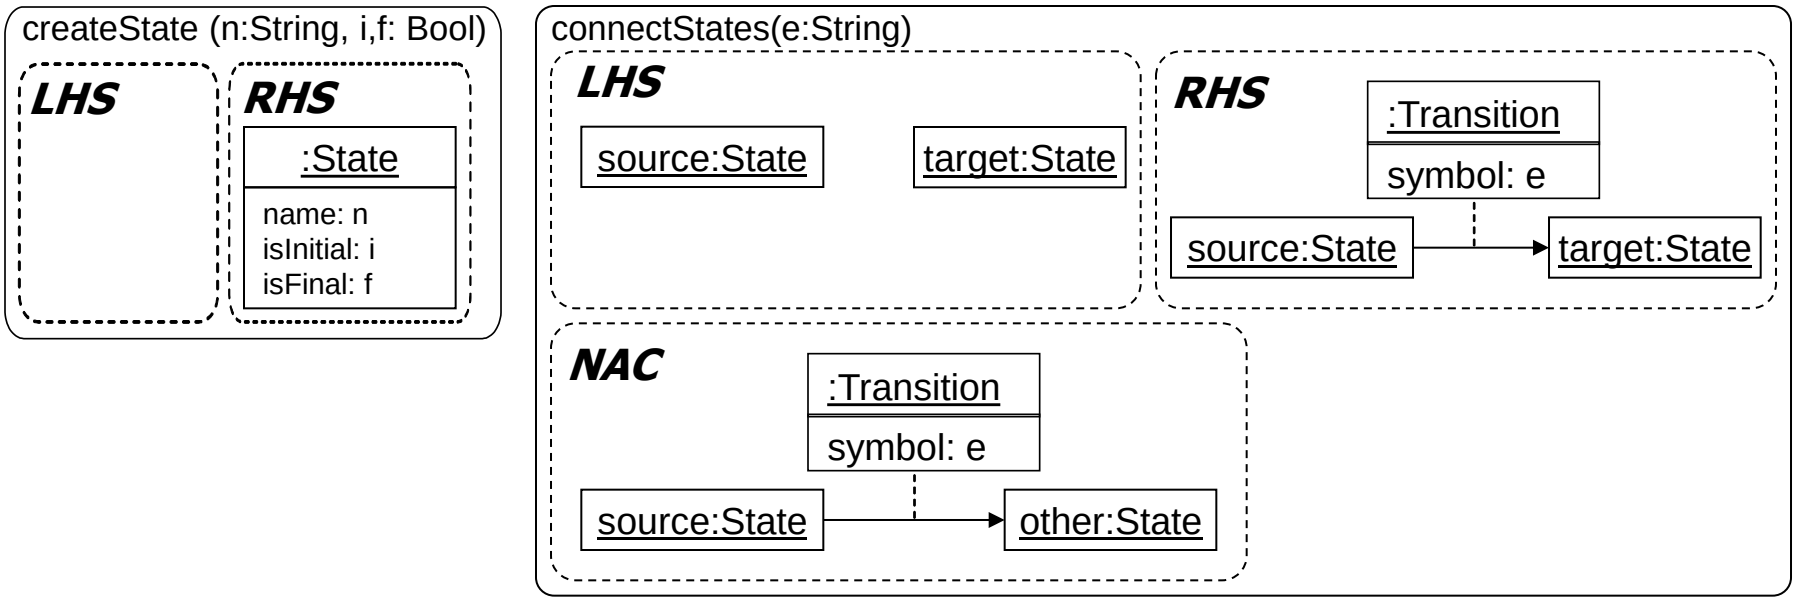
Exercise, Finite automata

- Build a creation grammar for deterministic finite automata, which generates the same language as the following meta-model:



Graph transformation

Exercise, Finite automata



Additional graph constraints:
